

Canagliflozin

Invokana®
Oral hypoglycemic

FORMULATION

Each 100 mg tablet contains 102 mg canagliflozin hemihydrate, equivalent to 100 mg canagliflozin.
Each 300 mg tablet contains 306 mg canagliflozin hemihydrate, equivalent to 300 mg canagliflozin.

PHARMACEUTICAL FORM

- Canagliflozin (Invokana®) 100 mg tablets are yellow, capsule-shaped, immediate-release, and film-coated, with “CFZ” on one side and “100” on the other side.
- Canagliflozin (Invokana®) 300 mg tablets are white, capsule-shaped, immediate-release, and film-coated, with “CFZ” on one side and “300” on the other side.

THERAPEUTIC INDICATIONS

Canagliflozin (Invokana®) is indicated as an adjunct to diet and exercise to improve glycemic control in adults with type 2 diabetes mellitus.

Canagliflozin (Invokana®) is indicated to reduce the risk of major adverse cardiovascular events (cardiovascular death, nonfatal myocardial infarction and nonfatal stroke) in adults with type 2 diabetes mellitus who have established cardiovascular disease (CVD) or at least two risk factors for CVD.

Canagliflozin (Invokana®) is indicated for the treatment of diabetic kidney disease with albuminuria in adults with type 2 diabetes mellitus. In this population, Canagliflozin (Invokana®) reduces the risk of end-stage kidney disease (ESKD), doubling of serum creatinine, renal or cardiovascular (CV) death, and hospitalization for heart failure.

Limitation of Use

Canagliflozin (Invokana®) is not recommended in patients with type 1 diabetes mellitus or for the treatment of diabetic ketoacidosis.

POSODOLOGY AND METHOD OF ADMINISTRATION

Dosage – Adults 18 years of age and older

The recommended dose of Canagliflozin (Invokana®) is 100 mg or 300 mg once daily. See Table 1 for dosage recommendations based on estimated glomerular filtration rate (eGFR). The 300 mg dose may be considered for patients with an eGFR \geq 60 mL/min/1.73 m² [CrCl \geq 60 mL/min], who need tighter glycemic control and who have a low risk of adverse reactions associated with reduced intravascular volume with Canagliflozin (Invokana®) treatment (see below and Special Warnings and Special Precautions for Use).

A starting dose of 100 mg once daily should be used in patients on loop diuretics and patients \geq 75 years of age. In patients with evidence of reduced intravascular volume, correcting this condition prior to initiation of Canagliflozin (Invokana®) is recommended. For those patients who are tolerating Canagliflozin (Invokana®) 100 mg and who need tighter glycemic control, the dose can be increased to Canagliflozin (Invokana®) 300 mg (see **Special Warnings and Special Precautions for Use**).

When Canagliflozin (Invokana®) is used as add-on therapy with insulin or an insulin secretagogue (e.g. sulfonylurea), a lower dose of insulin or the insulin secretagogue may be considered to reduce the risk of hypoglycemia (see **Special Warnings and Special Precautions for Use** and **Undesirable Effects**).

Table 1: Dosage recommendation by eGFR

eGFR (mL/min/1.73 m ²) or CrCl (mL/min)	Dosage Recommendation
≥ 60	100 mg orally once daily, taken before the first meal of the day. Dose can be increased to 300 mg once daily for additional glycemic control.
30 to < 60	100 mg once daily.
<30	Initiation is not recommended; however patients with albuminuria greater than 300 mg/day may continue 100 mg once daily to reduce the risk of ESKD, doubling of serum creatinine, CV death, and hospitalization for heart failure.*

* In CREDESCENCE, treatment with Canagliflozin (Invokana[®]) 100 mg was continued in patients until the initiation of dialysis or in the event of renal transplantation.

Administration

Canagliflozin (Invokana[®]) should be taken orally once a day, preferably before the first meal of the day (see **Pharmacokinetic Properties**). Tablets are to be swallowed whole.

Missed dose

If a dose is missed, it should be taken as soon as the patient remembers; however, a double dose should not be taken on the same day.

Special populations

Pediatrics (< 18 years of age)

The safety and efficacy of Canagliflozin (Invokana[®]) have not been established in pediatric patients.

Elderly

In patients ≥ 75 years of age, the starting dose of Canagliflozin (Invokana[®]) is 100 mg once daily. Renal function and risk of volume depletion should be taken into account (see **Special Warnings and Special Precautions for Use** and **Undesirable Effects**).

CONTRAINDICATIONS

Hypersensitivity to the active substance or to any of the excipients (see **Undesirable Effects**).

SPECIAL WARNINGS AND SPECIAL PRECAUTIONS FOR USE

General

The safety and effectiveness of Canagliflozin (Invokana[®]) in patients with type 1 diabetes have not been established. Use of Canagliflozin (Invokana[®]) should be avoided in these patients.

Canagliflozin (Invokana[®]) should not be used for the treatment of diabetic ketoacidosis (DKA).

The glycemic lowering efficacy of canagliflozin is reduced in patients with an eGFR < 45 mL/min/1.73 m² [CrCl < 45 mL/min] and likely absent in patients with an eGFR < 30 mL/min/1.73 m² [CrCl < 30 mL/min]; therefore, if further glycemic control is needed, the addition of other anti-hyperglycemic agents should be considered. For dose adjustment recommendations according to eGFR [CrCl] refer to Table 1.

Diabetic ketoacidosis

Patients with a history of diabetic ketoacidosis (DKA) were excluded from clinical studies. Canagliflozin (Invokana[®]) should be used with caution in patients with a history of DKA.

Rare cases of DKA, including life-threatening and fatal cases, have been reported in postmarketing surveillance in patients with type 1 and type 2 diabetes mellitus treated with SGLT2 inhibitors, including canagliflozin.

Type 1 diabetes mellitus

There is an increased risk of DKA in patients with type 1 diabetes mellitus who take Canagliflozin (Invokana®). In an 18-week clinical study (N=351), DKA was reported in 5.1% (6/117), 9.4% (11/117), and 0.0% (0/117) of patients on Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively. The DKA events required hospitalization in 12 patients. Five of these patients presented with blood glucose values less than 13.9 mmol/L [250 mg/dL]. Concomitant conditions (e.g., infection, cessation of insulin therapy) known to increase the risk of developing DKA were identified in most patients.

Type 2 diabetes mellitus

In patients with type 2 diabetes mellitus, DKA has been reported with the use of Canagliflozin (Invokana®). In the clinical development program, including two long-term cardiovascular events, events of DKA were reported in 0.2% (17/11,078) of patients treated with Canagliflozin (Invokana®), all of whom were hospitalized. DKA has also been reported during postmarketing surveillance and has occurred in patients with blood glucose values less than 13.9 mmol/L [250 mg/dL] (see **Undesirable Effects**).

Therefore, in patients with type 2 diabetes presenting with metabolic acidosis, a diagnosis of DKA should be considered even if blood glucose levels are less than 13.9 mmol/L [250 mg/dL]. Patients on Canagliflozin (Invokana®) should be tested for ketones when they present with signs and symptoms of metabolic acidosis, such as difficulty breathing, nausea, vomiting, abdominal pain, feeling confused, fruity-smelling breath, and unusual fatigue or sleepiness, in order to prevent delayed diagnosis and to ensure appropriate patient management.

In patients with type 2 diabetes with DKA, treatment with Canagliflozin (Invokana®) should be discontinued immediately. Temporarily discontinue treatment with Canagliflozin (Invokana®) in patients with type 2 diabetes who are hospitalized for major surgical procedures or acute serious medical illnesses. Monitoring for DKA is recommended in these patients. Based on canagliflozin half-life, glucosuria may persist longer than expected and DKA may be prolonged after discontinuation of Canagliflozin (Invokana®) in some patients (see **Pharmacokinetic Properties**). Treatment with Canagliflozin (Invokana®) may be restarted once the patient's condition has stabilized.

Lower limb amputation

In long-term clinical studies of Canagliflozin (Invokana®) in type 2 diabetes patients with established cardiovascular disease (CVD) or at least two risk factors for CVD, Canagliflozin (Invokana®) was associated with an increased risk of lower limb amputation versus placebo (0.63 vs 0.34 events per 100 patient-years, respectively), and this increase occurred primarily of the toe and midfoot (see **Undesirable Effects**). In long-term clinical study in patients with type 2 diabetes and diabetic kidney disease, no difference in lower limb amputation risk was observed in patients treated with Canagliflozin (Invokana®) 100 mg relative to placebo. As an underlying mechanism has not been established, risk factors, apart from general risk factors, for amputation are unknown.

Before initiating Canagliflozin (Invokana®), consider factors in the patient history that may increase the risk for amputation. As precautionary measures, consideration should be given to carefully monitoring patients with a higher risk for amputation events and counselling patients about the importance of routine preventative foot care and maintaining adequate hydration. Consideration may also be given to stopping treatment with Canagliflozin (Invokana®) in patients who develop events which may precede amputation such as lower-extremity skin ulcer, infection, osteomyelitis or gangrene.

Reduced intravascular volume

Due to its mechanism of action, Canagliflozin (Invokana®) increases urinary glucose excretion (UGE) and induces an osmotic diuresis, which may reduce intravascular volume. Patients most susceptible to adverse

reactions related to reduced intravascular volume (e.g., postural dizziness, orthostatic hypotension, or hypotension) include patients on loop diuretics, patients with moderate renal impairment, and patients ≥ 75 years of age (see **Posology and Method of Administration** and **Undesirable Effects**).

In placebo-controlled clinical studies of Canagliflozin (Invokana[®]), increases in adverse reactions related to reduced intravascular volume were seen more commonly with the 300 mg dose and occurred most frequently in the first three months (see **Undesirable Effects**). Due to reduced intravascular volume, generally small mean dose-dependent increases in serum creatinine and concomitant decreases in eGFR were seen within the first six weeks of treatment initiation with Canagliflozin (Invokana[®]). In patients susceptible to greater reductions in intravascular volume as described above, larger decreases in eGFR ($> 30\%$) were sometimes seen, which subsequently improved, and infrequently required interruption of treatment with Canagliflozin (Invokana[®]) (see **Undesirable Effects**).

Patients should be advised to report symptoms of reduced intravascular volume. These adverse reactions infrequently led to discontinuation of Canagliflozin (Invokana[®]) and were often managed by modification of the blood pressure-lowering drug regimen (including diuretics) while continuing therapy with Canagliflozin (Invokana[®]). In patients with volume depletion, correcting this condition prior to initiation of Canagliflozin (Invokana[®]) is recommended.

Renal function should be assessed prior to initiation of Canagliflozin (Invokana[®]). More frequent renal function monitoring is recommended in patients with an eGFR < 60 mL/min/1.73 m² [CrCl < 60 mL/min].

Hypoglycemia in add-on therapy with other antihyperglycemic agents

When used alone or as add-on therapy with antihyperglycemic agents not associated with hypoglycemia, Canagliflozin (Invokana[®]) showed a low incidence of hypoglycemia. Insulin and insulin secretagogues (e.g., sulfonylurea) are known to cause hypoglycemia. When Canagliflozin (Invokana[®]) was used as add-on therapy with insulin or an insulin secretagogue (e.g., sulfonylurea), the incidence of hypoglycemia was increased over that of placebo.

Therefore, to lower the risk of hypoglycemia, a dose reduction of insulin or an insulin secretagogue may be considered (see **Posology and Method of Administration** and **Undesirable Effects**).

Necrotizing fasciitis of the perineum (Fournier's gangrene)

Reports of necrotizing fasciitis of the perineum (Fournier's gangrene, a very rare but serious and potentially life-threatening necrotizing infection requiring urgent surgical intervention, have been identified in postmarketing surveillance in patients with diabetes mellitus receiving SGLT2 inhibitors, including Canagliflozin (Invokana[®]). Cases have been reported in both females and males. Serious outcomes have included hospitalization, multiple surgeries, and death.

Patients treated with Canagliflozin (Invokana[®]) presenting with pain or tenderness, erythema, or swelling in the genital or perineal area, along with fever or malaise, should be assessed for necrotizing fasciitis. If suspected, start treatment immediately with broad-spectrum antibiotics, and if necessary, surgical debridement. Discontinue Canagliflozin (Invokana[®]), closely monitor blood glucose levels, and provide appropriate alternative therapy for glycemic control.

Genital Mycotic Infections

Consistent with the mechanism of SGLT2 inhibition with increased UGE, vulvovaginal candidiasis in females and balanitis or balanoposthitis in males were reported in clinical studies (see **Undesirable Effects**). Male and female patients with a history of genital mycotic infections were more likely to develop an infection. Balanitis or balanoposthitis occurred primarily in uncircumcised male patients; events of phimosis were also reported. In a pooled analysis of 10 controlled studies, the incidence rate of circumcision was 0.38 events per 100 patient-years of exposure in uncircumcised male patients treated with canagliflozin. The majority of genital mycotic infections were treated with topical antifungal treatments, either prescribed by a healthcare professional or self-treated while continuing therapy with Canagliflozin (Invokana[®]).

INTERACTIONS WITH OTHER MEDICINAL PRODUCTS AND OTHER FORMS OF INTERACTIONS***In vitro assessment of interactions***

The metabolism of canagliflozin is primarily via glucuronide conjugation mediated by UDP glucuronosyl transferase 1A9 (UGT1A9) and 2B4 (UGT2B4).

In *in vitro* studies, canagliflozin neither inhibited cytochrome P450 CYP1A2, CYP2A6, CYP2C19, CYP2D6, or CYP2E1, CYP2B6, CYP2C8, CYP2C9, nor induced CYP1A2, CYP2C19, CYP2B6, CYP3A4 at higher than therapeutic concentrations. Canagliflozin weakly inhibited CYP3A4 *in vitro*; however, based upon a clinical study, no clinically relevant interaction was observed. Therefore, canagliflozin is not expected to alter the metabolic clearance of co-administered medicinal products that are metabolized by these enzymes.

Canagliflozin is a P-glycoprotein (P-gp) substrate and inhibits P-glycoprotein mediated transport of digoxin with low potency.

In vivo assessment of interactions

Specific drug interaction studies were conducted to investigate the effects of inhibitors or inducers of the drug-metabolizing enzymes UGT1A9 and UGT2B4 and transporters P-gp and MRP2 on canagliflozin pharmacokinetics, and also to assess the effects of canagliflozin on the pharmacokinetics of the P-gp substrate digoxin.

Effects of other drugs on canagliflozin

In clinical studies, the effects of other drugs on canagliflozin were assessed. Ciclosporin, hydrochlorothiazide, oral contraceptives (ethinyl estradiol and levonorgestrel), metformin, and probenecid had no clinically relevant effect on the pharmacokinetics of canagliflozin.

Rifampicin: Co-administration with rifampicin, a nonselective inducer of several UGT enzymes and drug transporters including UGT1A9, UGT2B4, P-gp, and MRP2, decreased canagliflozin exposure. These decreases in exposure to canagliflozin may decrease efficacy. If a combined inducer of these UGTs and drug transport systems (e.g., rifampicin, phenytoin, barbiturates, phenobarbital, ritonavir, carbamazepine, efavirenz, St. John's wort [*Hypericum perforatum*]) must be co-administered with Canagliflozin (Invokana®), monitor HbA_{1c} in patients receiving Canagliflozin (Invokana®) 100 mg once daily with consideration to increasing the dose to 300 mg once daily if additional glycemic control is needed. In patients with an eGFR 45 to < 60 mL/min/1.73 m² [CrCl 45 to < 60 mL/min], taking Canagliflozin (Invokana®) 100 mg who are receiving concurrent therapy with a UGT enzyme inducer and who require additional glycemic control, other antihyperglycemic therapies should be considered.

Table 2. Effect of Co-Administered Drugs on Systemic Exposure of Canagliflozin

Co-Administered Drug	Dose of Co-Administered Drug ¹	Dose of Canagliflozin ¹	Geometric Mean Ratio (Ratio With/Without Co-Administered Drug) No Effect=1.0	
			AUC ² (90% CI)	C _{max} (90% CI)
No dose adjustments of Canagliflozin (Invokana®) required for the following:				
Ciclosporin	400 mg	300 mg once daily for 8 days	1.23 (1.19; 1.27)	1.01 (0.91; 1.11)
Ethinyl estradiol and levonorgestrel	0.03 mg ethinyl estradiol and 0.15 mg levonorgestrel	200 mg once daily for 6 days	0.91 (0.88; 0.94)	0.92 (0.84; 0.99)
Hydrochlorothiazide	25 mg once daily for 35 days	300 mg once daily for 7 days	1.12 (1.08; 1.17)	1.15 (1.06; 1.25)

Table 2. Effect of Co-Administered Drugs on Systemic Exposure of Canagliflozin

Co-Administered Drug	Dose of Co-Administered Drug ¹	Dose of Canagliflozin ¹	Geometric Mean Ratio (Ratio With/Without Co-Administered Drug) No Effect=1.0	
			AUC ² (90% CI)	C _{max} (90% CI)
Metformin	2000 mg	300 mg once daily for 8 days	1.10 (1.05; 1.15)	1.05 (0.96; 1.16)
Probenecid	500 mg twice daily for 3 days	300 mg once daily for 17 days	1.21 (1.16; 1.25)	1.13 (1.00; 1.28)
Rifampicin	600 mg once daily for 8 days	300 mg	0.49 (0.44; 0.54)	0.72 (0.61; 0.84)

¹ Single dose unless otherwise noted

² AUC_{inf} for drugs given as a single dose and AUC_{24h} for drugs given as multiple doses.

Effects of canagliflozin on other drugs

In interaction studies conducted in healthy subjects, canagliflozin at steady-state had no clinically relevant effect on the pharmacokinetics of metformin, oral contraceptives (ethinyl estradiol and levonorgestrel), glyburide, simvastatin, paracetamol, hydrochlorothiazide, or warfarin.

Digoxin: The combination of canagliflozin 300 mg once daily for 7 days with a single dose of digoxin 0.5 mg followed by 0.25 mg daily for 6 days resulted in a 20% increase in AUC and a 36% increase in C_{max} of digoxin, possibly due to an interaction at the level of P-gp. Patients taking digoxin or other cardiac glycosides (e.g., digitoxin) should be monitored appropriately.

Table 3. Effect of Canagliflozin on Systemic Exposure of Co-Administered Drugs

Co-Administered Drug	Dose of Co-Administered Drug ¹	Dose of Canagliflozin ¹	Geometric Mean Ratio (Ratio With/Without Co-Administered Drugs) No Effect = 1.0		
				AUC ² (90% CI)	C _{max} (90% CI)
No dose adjustments of co-administered drug required for the following:					
Digoxin	0.5 mg once daily first day followed by 0.25 mg once daily for 6 days	300 mg once daily for 7 days	digoxin	1.20 (1.12; 1.28)	1.36 (1.21; 1.53)
Ethinyl estradiol and levonorgestrel	0.03 mg ethinyl estradiol and 0.15 mg levonorgestrel	200 mg once daily for 6 days	ethinyl estradiol	1.07 (0.99; 1.15)	1.22 (1.10; 1.35)
			levonorgestrel	1.06 (1.00; 1.13)	1.22 (1.11; 1.35)
Glyburide	1.25 mg	200 mg once daily for 6 days	glyburide	1.02 (0.98; 1.07)	0.93 (0.85; 1.01)
			3-cis-hydroxy-glyburide	1.01 (0.96; 1.07)	0.99 (0.91; 1.08)
			4-trans-hydroxy-glyburide	1.03 (0.97; 1.09)	0.96 (0.88; 1.04)
Hydrochlorothiazide	25 mg once daily for 35 days	300 mg once daily for 7 days	hydrochlorothiazide	0.99 (0.95; 1.04)	0.94 (0.87; 1.01)

Table 3. Effect of Canagliflozin on Systemic Exposure of Co-Administered Drugs

Co-Administered Drug	Dose of Co-Administered Drug ¹	Dose of Canagliflozin ¹	Geometric Mean Ratio (Ratio With/Without Co-Administered Drugs) No Effect = 1.0		
				AUC ² (90% CI)	C _{max} (90% CI)
Metformin	2000 mg	300 mg once daily for 8 days	metformin	1.20 (1.08; 1.34)	1.06 (0.93; 1.20)
Paracetamol	1000 mg	300 mg twice daily for 25 days	paracetamol	1.06 ³ (0.98; 1.14)	1.00 (0.92; 1.09)

³ AUC_{0-12h}

Drug/Laboratory test interference

1,5-AG assay

Increases in urinary glucose excretion with Canagliflozin (Invokana[®]) can falsely lower 1,5-anhydroglucitol (1,5 AG) levels and make measurements of 1,5 AG unreliable in assessing glycemic control. Therefore, 1,5-AG assays should not be used for assessment of glycemic control in patients on canagliflozin. For further detail, it may be advisable to contact the specific manufacturer of the 1,5-AG assay.

Urine glucose test

Due to its mechanism of action, patients taking Canagliflozin (Invokana[®]) will test positive for glucose in their urine.

PREGNANCY, BREAST-FEEDING AND FERTILITY

Pregnancy

Pregnancy Category C

There are no adequate and well-controlled studies in pregnant women. Animal studies do not indicate direct or indirect harmful effects with respect to reproductive toxicity (see **Non-Clinical Information**). During pregnancy, consider appropriate alternative therapies, especially during the second and third trimesters. Canagliflozin (Invokana[®]) should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Breast-feeding

Available pharmacodynamic/toxicological data in animals have shown excretion of canagliflozin in milk. It is not known if canagliflozin is excreted in human milk. A risk to the breast-fed child cannot be excluded. A decision must be made whether to discontinue breast-feeding or to discontinue Canagliflozin (Invokana[®]) therapy, taking into account the benefit of breast-feeding for the child and the benefit of therapy for the woman (see **Non-Clinical Information**).

Fertility

The effect of canagliflozin on fertility in humans has not been studied. No effects on fertility were

observed in animal studies (see **Non-Clinical Information**).

EFFECTS ON ABILITY TO DRIVE AND USE MACHINES

Canagliflozin has no known influence on the ability to drive and use machines. However, patients should be alerted to the risk of hypoglycemia when Canagliflozin (Invokana®) is used as add-on therapy with insulin or an insulin secretagogue, and to the elevated risk of adverse reactions related to reduced intravascular volume, such as postural dizziness (see **Posology and Method of Administration, Special Warnings and Special Precautions for Use**, and **Undesirable Effects**).

UNDESIRABLE EFFECTS

Throughout this section, adverse reactions are presented. Adverse reactions are adverse events that were considered to be reasonably associated with the use of canagliflozin based on the comprehensive assessment of the available adverse event information. A causal relationship with canagliflozin cannot be reliably established in individual cases. Further, because clinical studies are conducted under widely varying conditions, adverse reaction rates observed in the clinical studies of a drug cannot be directly compared to rates in the clinical studies of another drug and may not reflect the rates observed in clinical practice.

The safety of Canagliflozin (Invokana®) was evaluated in 22,645 patients with type 2 diabetes, including 13,278 patients treated with Canagliflozin (Invokana®) and 9,367 patients treated with comparator in 15 double-blind, controlled Phase 3 and Phase 4 clinical studies. A total of 10,134 patients were treated in two dedicated cardiovascular studies, for a mean exposure duration of 149 weeks (223 weeks in CANVAS and 94 weeks in CANVAS-R), and 8,114 patients treated in 12 double-blind, controlled Phase 3 and Phase 4 clinical studies, for a mean follow-up duration of 49 weeks. In a dedicated renal outcomes study, a total of 4,397 patients with diabetic kidney disease had a mean duration of drug exposure of 115 weeks and a mean follow-up duration of 136 weeks.

Safety analyses were conducted in patients who received Canagliflozin (Invokana®) as monotherapy or as add-on therapy with other antihyperglycemic agents. Canagliflozin (Invokana®) was studied as monotherapy in one placebo-controlled study of 26 weeks duration, which included an active-treatment substudy in patients with more severe hyperglycemia [$HbA_{1c} (A_{1c}) > 10$ and $\leq 12\%$]. Five placebo- or active-controlled studies investigated Canagliflozin (Invokana®) as add-on therapy with other antihyperglycemic agents: two with metformin (26 and 52 weeks); two with metformin and sulfonylurea (26 and 52 weeks), and one with metformin and pioglitazone (26 weeks). Two placebo-controlled studies investigated the use of Canagliflozin (Invokana®) added on to the current diabetes treatment regimen, one in older patients and one in patients with moderate renal impairment. Cardiovascular studies were completed in patients with type 2 diabetes; safety analyses were conducted that investigated Canagliflozin (Invokana®) as add-on therapy with a sulfonylurea and with insulin.

The primary assessment of safety and tolerability was conducted in a pooled analysis (N=2313) of four 26-week placebo-controlled clinical studies (monotherapy and add-on therapy with metformin, metformin and sulfonylurea, and metformin and pioglitazone). The most commonly reported adverse reactions during treatment ($\geq 5\%$) were vulvovaginal candidiasis, urinary tract infection, and polyuria or pollakiuria. Adverse reactions leading to discontinuation of $\geq 0.5\%$ of all Canagliflozin (Invokana®)-treated patients in these studies were vulvovaginal candidiasis (0.7% of females) and balanitis or balanoposthitis (0.5% of males). Additional safety analyses (including long-term data) across the entire canagliflozin program (placebo- and active-controlled studies) were conducted to assess reported adverse events in order to identify adverse reactions.

Table 4 lists adverse reactions reported in $\geq 2\%$ of Canagliflozin (Invokana®)-treated patients in the four pooled, 26-week, placebo-controlled clinical studies (N=2313).

Table 4. Adverse Reactions From Four Pooled 26-Week Placebo-Controlled Studies¹ Reported in ≥ 2% of Canagliflozin (Invokana[®])-Treated Patients

System Organ Class Adverse Reaction	Canagliflozin (Invokana [®]) 100 mg N=833 %	Canagliflozin (Invokana [®]) 300 mg N=834 %	Placebo N=646 %
Gastrointestinal disorders			
Constipation	15 (1.8)	19 (2.3)	6 (0.9)
Nausea	18 (2.2)	19 (2.3)	10 (1.5)
Thirst ²	23 (2.8)	19 (2.3)	1 (0.2)
Renal and urinary disorders			
Polyuria or Pollakiuria ³	44 (5.3)	38 (4.6)	5 (0.8)
Urinary tract infection ⁴	49 (5.9)	36 (4.3)	26 (4.0)
Reproductive system and breast disorders			
Balanitis or Balanoposthitis ⁵	17 (4.2)	15 (3.7)	2 (0.6)
Vulvovaginal candidiasis ⁶	44 (10.4)	49 (11.4)	10 (3.2)

¹ Includes monotherapy and add-on therapy with metformin, metformin and sulfonylurea, and metformin and pioglitazone.

² Thirst includes the terms Thirst (1.3%, 1.9%, 0.2%) with incidences for Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo, respectively, and also includes the terms Dry mouth and Polydipsia with incidences < 1% in any treatment group.

³ Polyuria or Pollakiuria includes the terms Polyuria (0.7%, 1.4%, 0.0%) and Pollakiuria (4.2%, 3.1%, 0.6%) with incidences for Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo, respectively, and also includes the terms Urine output increased, Micturition urgency, and Nocturia with incidences < 1% in any treatment group.

⁴ Urinary tract infection includes the term Urinary tract infection (5.5%, 4.1%, 4.0%) with incidences for Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo, respectively, and also includes the terms Cystitis, Kidney infection, and Urosepsis with incidences < 1% in any treatment group. There was no imbalance among Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo for kidney infection or urosepsis.

⁵ Balanitis or Balanoposthitis includes the terms Balanitis (2.2%, 1.7%, 0.0%) and Balanoposthitis (1.0%, 0.7%, 0.3%) with incidences for Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo, respectively, and also includes the terms Balanitis candida and Genital infection fungal with incidences < 1% in any treatment group.

⁶ Vulvovaginal candidiasis includes the terms Vulvovaginal candidiasis (1.6%, 2.8%, 1.0%), Vulvovaginal mycotic infection (5.9%, 5.3%, 1.3%), Vulvovaginitis (1.9%, 1.6%, 0.0%), and Vaginal infection (1.2%, 1.6%, 0.6%) with incidences for Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, and placebo, respectively, and also includes the terms Vulvitis and Genital infection fungal with incidences < 1% in any treatment group.

Other adverse reactions in clinical studies of Canagliflozin (Invokana[®]) that occurred at a rate < 2% in placebo-controlled studies were adverse reactions related to reduced intravascular volume (postural dizziness, orthostatic hypotension, hypotension, dehydration, and syncope) (see below), skin rash, and urticaria.

The type and frequency of common adverse reactions observed in both the dedicated cardiovascular safety program and dedicated renal outcomes study with long-term follow up were consistent with those listed in Table 4.

Description of selected adverse reactions

Diabetic ketoacidosis

DKA was identified as an adverse reaction during postmarketing surveillance. In a review of the data from the type 2 diabetes mellitus clinical development program, incidence rates of adjudicated events of DKA were 0.06 (0.2%, 17/11,078) and 0.02 (0.1%, 4/7,170) per 100 patient-years of follow-up with Canagliflozin (Invokana[®]) combined dose groups, and comparator, respectively. Of the 17 patients on Canagliflozin (Invokana[®]), 4 (3 on Canagliflozin (Invokana[®]) 100 mg, 1 on Canagliflozin (Invokana[®]) 300 mg) were reported to have autoimmune diabetes (latent autoimmune diabetes of adulthood [LADA] or type 1 diabetes) or tested positive for GAD65 antibodies while no patients on comparator were diagnosed with autoimmune diabetes and 16 of the 17 patients were receiving insulin therapy (insulin use was unknown in one patient). The blood glucose values in 13 patients on Canagliflozin (Invokana[®]) around the time of admission ranged from 19.3 mmol/L [347 mg/dL] to 31.7 mmol/L [571 mg/dL]. Four patients had blood glucose values ranging from 8.2 mmol/L [148 mg/dL] to 17.8 mmol/L [320 mg/dL] (see **Special Warnings and Special Precautions for Use**).

In a long-term renal outcomes study in patients with type 2 diabetes and diabetic kidney disease, incidence rates of adjudicated events of DKA were 0.21 (0.5%, 12/2,200) and 0.03 (0.1%, 2/2, 197) per 100 patient-years of follow-up with Canagliflozin (Invokana®) 100 mg and placebo, respectively; of the 14 patients with DKA, 8 (7 on canagliflozin 100 mg and 1 on placebo) had an eGFR before treatment of 30 to < 45 mL/min/1.73 m² [CrCl 30 to <45 mL/min].

Lower limb amputation

In patients with type 2 diabetes who had established cardiovascular disease or at least two risk factors for cardiovascular disease, Canagliflozin (Invokana®) was associated with an increased risk of lower limb amputation as observed in the Integrated CANVAS Program comprised of CANVAS and CANVAS-R, two large, long-term, randomized, placebo-controlled studies evaluating 10,134 patients. The imbalance occurred as early as the first 26 weeks of therapy. Patients in CANVAS and CANVAS-R were followed for an average of 5.7 and 2.1 years, respectively. Regardless of treatment with Canagliflozin (Invokana®) or placebo, the risk of amputation was highest in patients with a baseline history of prior amputation, peripheral vascular disease, and neuropathy. The risk of lower limb amputation was not dose-dependent. The amputation results for the Integrated CANVAS Program are shown in Table 5.

There was no difference in risk of lower limb amputations associated with the use of Canagliflozin (Invokana®) 100 mg relative to placebo (1.2 vs 1.1 events per 100 patient-years, respectively [HR: 1.11; 95% CI 0.79, 1.56]) in CREDENCE, a long-term renal outcomes study of 4,397 patients with type 2 diabetes and diabetic kidney disease (see **Special Warnings and Special Precautions for Use** and **Clinical Efficacy**). In other type 2 diabetes studies with Canagliflozin (Invokana®), which enrolled a general diabetic population of 8,114 patients, no difference in lower limb amputation risk was observed relative to control.

Table 5: Integrated Analysis of Amputations in CANVAS AND CANVAS-R

	Placebo N=4344	Canagliflozin (Invokana®) N=5790
Total number of subjects with events, n (%)	47 (1.1)	140 (2.4)
Incidence rate (per 100 subject-years)	0.34	0.63
HR (95% CI) vs. placebo		1.97 (1.41, 2.75)
Minor Amputation, n (%) *	34/47 (72.3)	99/140 (70.7)
Major Amputation, n (%) †	13/47 (27.7)	41/140 (29.3)

Note: Incidence is based on the number of patients with at least one amputation, and not the total number of amputation events. A patient's follow-up is calculated from Day 1 to the first amputation event date. Some patients had more than one amputation. The percentage of minor and major amputations is based on the highest-level amputation for each patient.

* Toe and midfoot

† Ankle, below knee and above knee

Of the subjects who had an amputation event, the toe and midfoot were the most frequent sites (71%) in both treatment groups (see Table 5). Multiple amputations (some involving both lower limbs) were observed infrequently and in similar proportions in both treatment groups.

Lower limb infections, diabetic foot ulcers, peripheral arterial disease, and gangrene, were the most common medical events associated with the need for an amputation in both treatment groups (see **Special Warnings and Special Precautions for Use**).

Reduced intravascular volume

In the pooled analysis of the four 26-week, placebo-controlled studies, the incidence of all adverse reactions related to reduced intravascular volume (e.g., postural dizziness, orthostatic hypotension, hypotension, dehydration, and syncope) was 1.2% for Canagliflozin (Invokana®) 100 mg, 1.3% for Canagliflozin (Invokana®) 300 mg, and 1.1% for placebo. The incidence with Canagliflozin (Invokana®) treatment in the two active-controlled studies was similar to comparators.

In one of the dedicated long-term cardiovascular studies (CANVAS), where patients were generally older with a higher prevalence of comorbidities, the incidence rates of adverse reactions related to reduced intravascular volume were 2.34 with Canagliflozin (Invokana®) 100 mg, 2.87 with Canagliflozin (Invokana®) 300 mg, and 1.85 with placebo, events per 100 patient-years of exposure.

To assess risk factors for these adverse reactions, a larger pooled analysis (N=12,441) of patients from 13 controlled Phase 3 and Phase 4 studies including both doses of Canagliflozin (Invokana®) was conducted. In this pooled analysis, patients on loop diuretics, patients with moderate renal impairment (eGFR 30 to < 60 mL/min/1.73 m²) [CrCl 30 to < 60 mL/min], and patients ≥ 75 years of age had higher incidences of these adverse reactions. For patients on loop diuretics, the incidence rates were 4.98 on Canagliflozin (Invokana®) 100 mg and 5.67 on Canagliflozin (Invokana®) 300 mg compared to 4.15 events per 100 patient-years of exposure in the control group. For patients with a baseline eGFR < 60 mL/min/1.73 m² [CrCl < 60 mL/min], the incidence rates were 5.24 on Canagliflozin (Invokana®) 100 mg and 5.35 on Canagliflozin (Invokana®) 300 mg compared to 3.11 events per 100 patient-years of exposure in the control group. In patients ≥ 75 years of age, the incidence rates were 5.27 on Canagliflozin (Invokana®) 100 mg and 6.08 on Canagliflozin (Invokana®) 300 mg compared to 2.41 events per 100 patient-years of exposure in the control group (see **Posology and Method of Administration, Special Warnings and Special Precautions for Use, and Pharmacokinetic Properties - Special populations**).

In the dedicated cardiovascular study and the larger pooled analysis, as well as in a dedicated renal outcomes study, discontinuations due to adverse reactions related to reduced intravascular volume and serious adverse reactions related to reduced intravascular volume were not increased with Canagliflozin (Invokana®).

Hypoglycemia in add-on therapy with insulin or insulin secretagogues

The frequency of hypoglycemia was low (< 6%) among treatment groups when used as monotherapy or as an add-on to antihyperglycemic agents not associated with hypoglycemia. When Canagliflozin (Invokana®) was used as add-on therapy with insulin or sulfonylurea, hypoglycemia was reported more frequently, which is consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to insulin or an insulin secretagogue (e.g., sulfonylurea). In the 18-week substudy when Canagliflozin (Invokana®) was added to insulin therapy, hypoglycemia was observed in 49.3%, 48.2%, and 36.8% of patients treated with Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively and severe hypoglycemia occurred in 1.8%, 2.7%, and 2.5% of patients treated with Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively. When Canagliflozin (Invokana®) was added to sulfonylurea therapy, hypoglycemia was observed in 4.1%, 12.5%, and 5.8% of patients treated with Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively (see **Posology and Method of Administration and Special Warnings and Special Precautions for Use**).

Necrotizing fasciitis of the perineum (Fournier's gangrene)

Fournier's gangrene was identified as a SGLT2i class adverse reaction based on spontaneous adverse event reporting. These events had not been previously identified as ADRs because there were very few subjects in the canagliflozin Phase 3 and Phase 4 clinical development program (including the CANVAS and CREDENCE programs) with adverse events of Fournier's gangrene (incidences were <0.1% in the canagliflozin and comparator groups). All 4 adverse events of Fournier's gangrene (2 subjects treated with canagliflozin and 2 subjects treated with comparator) in the canagliflozin Phase 3 and Phase 4 clinical development program were serious.

Based on frequencies observed in clinical trials, this adverse reaction is categorized as ‘rare’ ($\geq 1/10000$ to $< 1/1000$ [$\geq 0.01\%$ and $< 0.1\%$]) and ‘very rare’ based on spontaneous reporting rates (see Table 6).

Genital mycotic infections

Vulvovaginal candidiasis (including vulvovaginitis and vulvovaginal mycotic infection) was reported in 10.4% and 11.4% of female patients treated with Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg, respectively, compared to 3.2% in placebo-treated female patients. Most reports of vulvovaginal candidiasis occurred during the first four months of treatment with canagliflozin. Among female patients taking Canagliflozin (Invokana®), 2.3% experienced more than one infection. Overall, 0.7% of all female patients discontinued Canagliflozin (Invokana®) due to vulvovaginal candidiasis (see ***Special Warnings and Special Precautions for Use***).

Candidal balanitis or balanoposthitis was reported in 4.2% and 3.7% of male patients treated with Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg, respectively, compared to 0.6% in placebo-treated male patients. Among male patients taking Canagliflozin (Invokana®), 0.9% had more than one infection. Overall, 0.5% of male patients discontinued Canagliflozin (Invokana®) due to candidal balanitis or balanoposthitis.

The incidence rate of phimosis was 0.56 events per 100 patient-years of exposure in uncircumcised males in a pooled analysis of 10 controlled studies. In this pooled analysis, the incidence rate of circumcision was 0.38 events per 100 patient-years of exposure in male patients treated with canagliflozin (see ***Special Warnings and Special Precautions for Use***).

Urinary tract infections

Urinary tract infections were more frequently reported for Canagliflozin (Invokana®) 100 mg and 300 mg (5.9% versus 4.3%, respectively) compared to 4.0% with placebo. Most infections were mild to moderate with no increase in the occurrence of serious adverse events. Subjects responded to standard treatments while continuing canagliflozin treatment. The incidence of recurrent infections was not increased with canagliflozin.

Bone fracture

In a cardiovascular study (CANVAS) of 4,327 treated patients with established or at least two risk factors for cardiovascular disease, the incidence rates of all adjudicated bone fracture were 1.59, 1.79, and 1.09 per 100 patient-years of follow-up to Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively, with the fracture imbalance initially occurring within the first 26 weeks of therapy.

In two other long-term studies and in studies conducted in the general diabetes population, no difference in fracture risk was observed with Canagliflozin (Invokana®) relative to control. In a second cardiovascular study (CANVAS-R) of 5,807 treated patients with established or at least two risk factors for cardiovascular disease, the incidence rates of all adjudicated bone fracture were 1.14 and 1.32 events per 100 patient-years of follow-up to Canagliflozin (Invokana®) and placebo, respectively.

In a long-term renal outcomes study of 4,397 patients with type 2 diabetes and diabetic kidney disease, the incidence rates of all adjudicated bone fracture were 1.18 and 1.21 events per 100 patient-years of follow-up to Canagliflozin (Invokana®) 100 mg and placebo, respectively. In other type 2 diabetes studies with Canagliflozin (Invokana®), which enrolled a general diabetes population of 7,729 patients, and where bone fractures were adjudicated, the incidence rates of all adjudicated bone fracture were 1.18 and 1.08 events per 100 patient-years of follow-up to Canagliflozin (Invokana®) and control, respectively. After 104 weeks of treatment, canagliflozin did not adversely affect bone mineral density.

Laboratory tests

Laboratory values, described below, are derived from the pooled analysis of 26-week, placebo-controlled clinical studies unless otherwise noted.

Increases in serum potassium

Mean percent changes from baseline in blood potassium were 0.5% and 1.0% for Canagliflozin (Invokana[®]) 100 mg and 300 mg, respectively, compared to 0.6% for placebo. Episodes of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were seen in 4.4% of patients treated with Canagliflozin (Invokana[®]) 100 mg, 7.0% of patients treated with Canagliflozin (Invokana[®]) 300 mg, and 4.8% of patients treated with placebo. In general, elevations were mild (< 6.5 mEq/L), transient, and did not require specific treatment.

In a long-term renal outcomes study in patients with type 2 diabetes and diabetic kidney disease, no difference in serum potassium, no increase in adverse events of hyperkalemia, and no absolute (> 6.5 mEq/L) or relative (> upper limit of normal and > 15% increase from baseline increases in serum potassium were observed with Canagliflozin (Invokana[®]) 100 mg relative to placebo.

Increases in serum creatinine and blood urea nitrogen (BUN)

Mean percent changes from baseline in creatinine, with commensurate decreases in eGFR, were 2.8% and 4.0% for Canagliflozin (Invokana[®]) 100 mg and 300 mg, respectively, compared to 1.5% for placebo. Mean percent changes from baseline in BUN were 17.1% and 18.0% for Canagliflozin (Invokana[®]) 100 mg and 300 mg, respectively, compared to 2.7% for placebo. These changes were generally observed within six weeks of treatment initiation. Subsequently, serum creatinine concentrations gradually trended toward baseline and BUN levels remained stable.

The proportion of patients with larger decreases in eGFR (> 30%) from baseline, occurring at any time during treatment, was 2.0% with Canagliflozin (Invokana[®]) 100 mg and 4.1% with Canagliflozin (Invokana[®]) 300 mg relative to 2.1% with placebo. These decreases in eGFR were often transient with fewer patients having this level of decrease at study endpoint, occurring in 0.7% of patients with Canagliflozin (Invokana[®]) 100 mg, 1.4% patients with Canagliflozin (Invokana[®]) 300 mg, and 0.5% of placebo-treated patients (see ***Special Warnings and Special Precautions for Use***).

After discontinuation of Canagliflozin (Invokana[®]) therapy, these changes in laboratory values improved or returned to baseline.

In long-term cardiovascular outcome studies, patients treated with Canagliflozin (Invokana[®]) experienced an initial fall in mean eGFR that thereafter gradually increased over the duration of the studies (up to 6.5 years). Patients treated with placebo experienced a progressive decline in eGFR. The effect on eGFR reversed after treatment discontinuation suggesting acute hemodynamic changes may play a role in the renal function changes observed with Canagliflozin (Invokana[®]). Additionally, treatment with Canagliflozin (Invokana[®]) resulted in a delay in the progression to albuminuria, a marker of kidney injury.

In a long-term renal outcomes study in patients with type 2 diabetes and diabetic kidney disease, the incidence rate for renal-related adverse events was lower in the canagliflozin 100-mg group compared with placebo group (5.71 and 7.91 per 100 patient-years in Canagliflozin (Invokana[®]) 100 mg and placebo, respectively.) Patients treated with placebo experienced a progressive decline in eGFR, whereas patients treated with Canagliflozin (Invokana[®]) 100 mg experience an initial fall in mean eGFR that thereafter attenuated over time (up to 3.5 years). At the end of treatment, mean eGFR was 1.61 mL/min/1.73 m² lower in the placebo group compared to the Canagliflozin (Invokana[®]) 100 mg group (see ***Clinical Efficacy***).

Lipid changes

The mean percent changes from baseline relative to placebo for low density lipoprotein cholesterol (LDL-C) were 0.11 mmol/L [4.4 mg/dL] (4.5%) and 0.21 mmol/L [8.2 mg/dL] (8.0%) with Canagliflozin (Invokana[®]) 100 mg and Canagliflozin (Invokana[®]) 300 mg, respectively. Smaller increases in total cholesterol of 2.5% and 4.3% relative to placebo for Canagliflozin (Invokana[®]) 100 mg and Canagliflozin (Invokana[®]) 300 mg, respectively, were seen. Increases in high-density lipoprotein cholesterol (HDL-C) were 5.4%, and 6.3% relative to placebo for Canagliflozin (Invokana[®]) 100 mg and Canagliflozin (Invokana[®]) 300 mg, respectively. Increases in non-HDL-C relative to placebo were 0.05 mmol/L (1.5%) and 0.13 mmol/L (3.6%) with Canagliflozin (Invokana[®]) 100 mg and 300 mg, respectively. The LDL-C/HDL-C ratios did not change with either Canagliflozin (Invokana[®]) dose compared to placebo. Concentrations of ApoB and LDL-C particle number (measured in two studies) and non-HDL-C increased to a smaller extent compared to LDL-C changes.

Increases in hemoglobin

Mean changes (percent changes) from baseline in hemoglobin concentrations were 4.7 g/L (3.5%) with Canagliflozin (Invokana®) 100 mg, 5.1 g/L (3.8%) with Canagliflozin (Invokana®) 300 mg, and -1.8 g/L (-1.1%) with placebo. Commensurate small increases in the mean percent change from baseline in blood erythrocytes and hematocrit were observed. At the end of treatment, 4.0%, 2.7%, and 0.8% of patients treated with Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively, had hemoglobin levels above the upper limit of normal.

Increases in serum phosphate

Dose-related increases in serum phosphate levels were observed with Canagliflozin (Invokana®). In the pool of four placebo-controlled trials, the mean percent change in serum phosphate levels were 3.6% and 5.1% with Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg, respectively, compared to 1.5% with placebo. Episodes of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were seen in 0.6% and 1.6% of patients treated with Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, compared to 1.3% of patients treated with placebo.

Decreases in serum urate

Moderate decreases in the mean percent change from baseline in serum urate were observed in the Canagliflozin (Invokana®) 100 mg and 300 mg groups (-10.1% and -10.6%, respectively) compared with placebo, where a slight increase from baseline (1.9%) was observed. Decreases in serum urate in the Canagliflozin (Invokana®) groups were maximal or near maximal by Week 6 and maintained with dosing. A transient increase in urinary uric acid excretion was seen, which was not persistent. In a pooled analysis (N=9439) of patients from eight controlled Phase 3 studies including both doses of Canagliflozin (Invokana®), events of nephrolithiasis were not increased.

Adverse reactions in specific populations**Elderly patients**

The safety profile in elderly patients was generally consistent with that for younger patients. Patients ≥ 75 years of age had a higher incidence of adverse reactions related to reduced intravascular volume (such as postural dizziness, orthostatic hypotension, hypotension) with incidence rates of 5.27, 6.08, and 2.41 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and the control group, respectively. Decreases in eGFR (-3.41 and -4.67 mL/min/1.73 m²) were reported with Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, compared to the control group (-4.15 mL/min/1.73 m²) (see **Posology and Method of Administration** and **Special Warnings and Special Precautions for Use**).

Patients with Moderate Renal Impairment**Patients with Type 2 Diabetes Mellitus with an eGFR 30 to <60 mL/min/1.73 m² [CrCl 30 to < 60 mL/min]**

An analysis of a pooled patient population (N=1085) with moderate renal impairment (baseline eGFR 30 to < 60 mL/min/1.73 m² [CrCl 30 to < 60 mL/min]) was conducted. In this population the incidence rates of adverse reactions related to reduced intravascular volume were 5.27 with Canagliflozin (Invokana®) 100 mg and 5.13 with Canagliflozin (Invokana®) 300 mg relative to 3.14 per 100 patient-years of exposure for placebo (see **Posology and Method of Administration** and **Special Warnings and Special Precautions for Use**). Serum creatinine levels increased by 8.39 and 9.91 µmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 7.51 µmol/L with placebo. BUN levels increased by 0.99 and 0.94 mmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 0.48 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 7.33, 8.12, and 6.47 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 3.26 for subjects treated with Canagliflozin (Invokana®) 100 mg, 2.68 for Canagliflozin (Invokana®) 300 mg, and 3.71 events per 100 patient-years of exposure for placebo (see **Special Warnings and Special Precautions for Use**).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 4.89 with Canagliflozin (Invokana®) 100 mg, 6.09 with Canagliflozin (Invokana®) 300 mg and 5.43 events per 100 patient-years of exposure for placebo. Rare, more severe elevations were seen in patients with moderate renal impairment who had prior elevated potassium concentrations and/or who were on multiple medications that reduce potassium excretion, such as potassium-sparing diuretics and angiotensin-converting-enzyme (ACE) inhibitors. In general, elevations were transient and did not require specific treatment.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 2.04 with Canagliflozin (Invokana®) 100 mg, 2.86 with Canagliflozin (Invokana®) 300 mg and 0.76 events per 100 patient-years of exposure for placebo. In general, elevations were transient and did not require specific treatment.

Patients with Type 2 Diabetes Mellitus with an eGFR 45 to < 60 mL/min/1.73 m² [CrCl 45 to 60 mL/min]

An analysis of a pooled patient population (N=721) with baseline eGFR 45 to < 60 mL/min/1.73 m² [CrCl 45 to < 60 mL/min] was conducted. In this population the incidence rates of adverse reactions related to reduced intravascular volume were 4.61 for Canagliflozin (Invokana®) 100 mg and 4.37 for Canagliflozin (Invokana®) 300 mg relative to 3.00 events per 100 patient-years of exposure for placebo (see ***Posology and Method of Administration*** and ***Special Warnings and Special Precautions for Use***). Serum creatinine levels increased by 5.92 and 6.98 µmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 7.03 µmol/L with placebo. BUN levels increased by 0.92 and 0.77 mmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 0.57 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 5.17, 6.62, and 5.82 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 2.52 for patients treated with Canagliflozin (Invokana®) 100 mg, 1.91 for Canagliflozin (Invokana®) 300 mg, and 3.20 events per 100 patient-years of exposure for placebo (see ***Special Warnings and Special Precautions for Use***).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 4.11 for Canagliflozin (Invokana®) 100 mg, 4.33 for Canagliflozin (Invokana®) 300 mg, and 3.80 events per 100 patient-years of exposure for placebo. Rare, more severe elevations were seen in patients with moderate renal impairment who had prior elevated potassium concentrations and/or who were on multiple medications that reduce potassium excretion, such as potassium-sparing diuretics and angiotensin-converting-enzyme (ACE) inhibitors. In general, elevations were transient and did not require specific treatment.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 0.93 for Canagliflozin (Invokana®) 100 mg, 1.15 for Canagliflozin (Invokana®) 300 mg and 0.71 events per 100 patient-years of exposure for placebo. In general, elevations were transient and did not require specific treatment.

Patients with Type 2 Diabetes Mellitus with an eGFR 30 to < 45 mL/min/1.73m² [CrCl 30 to 45 mL/min]

An analysis of a pooled patient population (N=364) with baseline eGFR 30 to < 45 mL/min/1.73 m² [CrCl 30 to < 45 mL/min] was conducted. In this population the incidence rates of adverse reactions related to reduced intravascular volume were 4.42 with Canagliflozin (Invokana®) 100 mg and 7.02 with Canagliflozin (Invokana®) 300 mg relative to 3.24 per 100 patient-years of exposure for the placebo group (see ***Posology and Method of Administration*** and ***Special Warnings and Special Precautions for Use***). Serum creatinine levels increased by 13.07 and 15.68 µmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 8.02 µmol/L with placebo. BUN levels increased by 1.07 and 1.24 mmol/L for Canagliflozin (Invokana®) 100 mg and 300 mg, respectively, relative to 0.35 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 14.46, 12.07, and 9.14 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 5.70 for subjects treated with Canagliflozin (Invokana®) 100 mg, 4.69 for Canagliflozin (Invokana®) 300 mg, and 5.78 events per 100 patient-years of exposure for placebo (see ***Special Warnings and Special Precautions for Use***).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 7.45 with Canagliflozin (Invokana®) 100 mg, 10.74 with Canagliflozin (Invokana®) 300 mg and 12.04 events per 100 patient-years of exposure for placebo. Rare, more severe elevations were seen in patients with moderate

renal impairment who had prior elevated potassium concentrations and/or who were on multiple medications that reduce potassium excretion, such as potassium-sparing diuretics and angiotensin-converting-enzyme (ACE) inhibitors. In general, elevations were transient and did not require specific treatment.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 5.70 with Canagliflozin (Invokana®) 100 mg, 7.38 with Canagliflozin (Invokana®) 300 mg and 0.96 events per 100 patient-years of exposure for placebo. In general, elevations were transient and did not require specific treatment.

Patients with Type 2 Diabetes Mellitus and Diabetic Kidney Disease with an eGFR 30 to < 60 mL/min/1.73m² [CrCl 30 to <60 mL/min]

In the long-term renal outcomes study, for the subgroup of patients with an eGFR before treatment of 30 to < 60 mL/min/1.73 m² [CrCl 30 to < 60 mL/min] the incidence rates of adverse reactions related to reduced intravascular volume were 3.58 with Canagliflozin (Invokana®) 100 mg relative to 2.58 per 100 patient-years of exposure for placebo (see ***Posology and Method of Administration*** and ***Special Warnings and Special Precautions for Use***). Serum creatinine levels increased by 38.54 µmol/L with Canagliflozin (Invokana®) 100 mg, relative to 50.88 µmol/L with placebo. BUN levels increased by 1.94 with Canagliflozin (Invokana®) 100 mg, relative to 2.35 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 18.01 and 20.81 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 12.14 for subjects treated with Canagliflozin (Invokana®) 100 mg and 16.99 events per 100 patient-years of exposure for placebo (see ***Special Warnings and Special Precautions for Use***).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 8.23 with Canagliflozin (Invokana®) 100 mg and 8.79 events per 100 patient-years of exposure for placebo. No between group imbalance was observed in this study where 99.9% of subjects were on angiotensin-converting-enzyme (ACE) inhibitors or angiotensin II receptor blockers (ARBs) at baseline.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 3.13 with Canagliflozin (Invokana®) 100 mg and 3.67 events per 100 patient-years of exposure for placebo.

Patients with Type 2 Diabetes Mellitus and Diabetic Kidney Disease with an eGFR 45 to < 60 mL/min/1.73 m² [CrCl 45 to < 60 mL/min]

In the long-term renal outcomes study, for the subgroup of patients with an eGFR before treatment of 45 to < 60 mL/min/1.73 m² [CrCl 45 to < 60 mL/min] the incidence rates of adverse reactions related to reduced intravascular volume were 2.32 with Canagliflozin (Invokana®) 100 mg relative to 2.57 per 100 patient-years of exposure for placebo (see ***Posology and Method of Administration*** and ***Special Warnings and Special Precautions for Use***). Serum creatinine levels increased by 28.81 µmol/L with Canagliflozin (Invokana®) 100 mg, relative to 39.57 µmol/L with placebo. BUN levels increased by 1.68 with Canagliflozin (Invokana®) 100 mg, relative to 1.87 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 16.94 and 18.54 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 10.80 for subjects treated with Canagliflozin (Invokana®) 100 mg and 14.13 events per 100 patient-years of exposure for placebo (see ***Special Warnings and Special Precautions for Use***).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 7.45 with Canagliflozin (Invokana®) 100 mg and 7.58 events per 100 patient-years of exposure for placebo. No between group imbalance was observed in this study where 99.9% of subjects were on angiotensin-converting-enzyme (ACE) inhibitors or angiotensin II receptor blockers (ARBs) at baseline.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 2.19 with Canagliflozin (Invokana®) 100 mg and 3.24 events per 100 patient-years of exposure for placebo.

Patients with Type 2 Diabetes Mellitus and Diabetic Kidney Disease with an eGFR 30 to < 45 mL/min/1.73 m² [CrCl 30 to < 45 mL/min]

In the long-term renal outcomes study, for the subgroup of patients with an eGFR before treatment of 30 to < 45 mL/min/1.73 m² [CrCl 30 to < 45 mL/min] the incidence rates of adverse reactions related to reduced intravascular volume were 4.91 with Canagliflozin (Invokana®) 100 mg relative to 2.60 per 100 patient-years of exposure for placebo (see **Posology and Method of Administration** and **Special Warnings and Special Precautions for Use**). Serum creatinine levels increased by 48.12 µmol/L with Canagliflozin (Invokana®) 100 mg, relative to 61.96 µmol/L with placebo. BUN levels increased by 2.20 with Canagliflozin (Invokana®) 100 mg, relative to 2.81 mmol/L with placebo. The incidence rates of decreases in eGFR (> 30%) at any time during treatment were 19.15 and 23.11 events per 100 patient-years of exposure for Canagliflozin (Invokana®) 100 mg and placebo, respectively. At the last post-baseline value, incidence rates for such decreases were 13.57 for subjects treated with Canagliflozin (Invokana®) 100 mg and 19.90 events per 100 patient-years of exposure for placebo (see **Special Warnings and Special Precautions for Use**).

The incidence rates of elevated serum potassium (> 5.4 mEq/L and 15% above baseline) were 9.07 with Canagliflozin (Invokana®) 100 mg and 10.02 events per 100 patient-years of exposure for placebo. No between group imbalance was observed in this study where 99.9% of subjects were on angiotensin-converting-enzyme (ACE) inhibitors or angiotensin II receptor blockers (ARBs) at baseline.

The incidence rates of elevated serum phosphate (> 1.65 mmol/L and 25% above baseline) were 4.14 with Canagliflozin (Invokana®) 100 mg and 4.11 events per 100 patient-years of exposure for placebo.

Postmarketing data

In addition to the adverse reactions identified from clinical studies, the following adverse reactions have been identified during postmarketing experience. Because these reactions were reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure. In the table, the frequencies are provided according to the following convention:

Very common	≥ 1/10 (≥ 10%)
Common	≥ 1/100 and < 1/10 (≥ 1% and < 10%)
Uncommon	≥ 1/1000 and < 1/100 (≥ 0.1% and < 1%)
Rare	≥ 1/10000 and < 1/1000 (≥ 0.01% and < 0.1%)
Very rare	< 1/10000, including isolated reports (< 0.01%).
Not known	Cannot be estimated from the available data.

Table 6: Adverse Reactions Identified During Postmarketing Experience with Canagliflozin (Invokana®)

System Organ Class Adverse Reaction	Frequency Category Estimated from Spontaneous Reporting Rates*	Frequency Category Estimated from Clinical Studies
Metabolism and nutrition disorders		
Diabetic ketoacidosis	Very rare	Rare [†]
Immune system disorders		
Anaphylactic reaction	Very rare	Rare [§]
Skin and subcutaneous tissue disorders		
Angioedema	Very rare	Rare [§]
Renal and urinary disorders		
Pyelonephritis	Very rare	Uncommon [‡]
Renal failure (mainly related to volume depletion)	Very rare	Uncommon [†]
Urosepsis	Very rare	Rare [§]
Infections and infestations		
Fournier's gangrene (necrotizing fasciitis of the perineum)	Very rare	Rare [§]

* Postmarketing spontaneous reporting rates were based on estimated exposure of person-years of treatment

[†] Phase 3 and Phase 4 clinical studies, including Non-CANVAS/Non-CREDENCE studies and CANVAS Program

[‡] Non-CANVAS/Non-CREDENCE, CANVAS-INT6, and CREDENCE clinical studies

[§] Phase 3 and Phase 4 clinical studies, including CANVAS and CREDENCE Program

OVERDOSE

Symptoms and signs

Single doses up to 1600 mg of Canagliflozin (Invokana®) in healthy subjects and Canagliflozin (Invokana®) 300 mg twice daily for 12 weeks in patients with type 2 diabetes were generally well-tolerated.

Treatment

In the event of an overdose, it is reasonable to employ the usual supportive measures, e.g., remove unabsorbed material from the gastrointestinal tract, employ clinical monitoring, and institute supportive treatment as dictated by the patient's clinical status. Canagliflozin was negligibly removed during a 4-hour hemodialysis session. Canagliflozin is not expected to be dialyzable by peritoneal dialysis.

PHARMACOLOGICAL PROPERTIES

Pharmacodynamic Properties

Mechanism of action

Sodium-glucose co-transporter 2 (SGLT2), expressed in the proximal renal tubules, is responsible for the majority of the reabsorption of filtered glucose from the tubular lumen. Patients with diabetes have been shown to have elevated renal glucose reabsorption which may contribute to persistent elevated glucose concentrations. Canagliflozin is an orally-active inhibitor of SGLT2. By inhibiting SGLT2, canagliflozin reduces reabsorption of filtered glucose and lowers the renal threshold for glucose (RT_G), and thereby increases urinary glucose excretion (UGE), lowering elevated plasma glucose concentrations by this insulin-independent mechanism in patients with type 2 diabetes. The increased urinary glucose excretion with SGLT2 inhibition also translates to an osmotic diuresis, with the diuretic effect leading to a reduction in systolic blood pressure; the increase in urinary glucose excretion results in a loss of calories and therefore a reduction in body weight, as has been demonstrated in studies of patients with type 2 diabetes.

Canagliflozin's action to increase UGE directly lowering plasma glucose is independent of insulin. Improvement in homeostasis model assessment for beta-cell function (HOMA beta-cell) and improved beta-cell insulin secretion response to a mixed-meal challenge has been observed in clinical studies with Canagliflozin (Invokana®).

In Phase 3 studies, pre-meal administration of canagliflozin 300 mg provided a greater reduction in post-meal glucose excursion than observed with the 100 mg dose. This effect at the 300 mg dose of canagliflozin may, in part, be due to local inhibition of intestinal SGLT1 (an important intestinal glucose co-transporter) related to transient high concentrations of canagliflozin in the intestinal lumen prior to drug absorption (canagliflozin is a low potency inhibitor of SGLT1). Studies have shown no glucose malabsorption with canagliflozin.

Canagliflozin increases the delivery of sodium to the distal tubule by blocking SGLT2-dependent glucose and sodium reabsorption thereby increasing tubuloglomerular feedback, which is associated with a reduction in intraglomerular pressure and a decrease in hyperfiltration in preclinical models of diabetes and clinical studies, with the potential for a renal protective effect. As the mechanism of renal protection by canagliflozin is known to occur at the level of the individual nephron and independently of glycemic control (which is an aggregate effect of functional nephrons), the effect on prevention of deterioration of renal function would be expected to be seen even in patients with impaired renal function.

Pharmacodynamic effects

Following single and multiple oral doses of canagliflozin to patients with type 2 diabetes, dose-dependent decreases in RT_G and increases in urinary glucose excretion were observed. From a starting value of RT_G of approximately 13 mmol/L, maximal suppression of 24-hour mean RT_G was seen with the 300 mg daily dose to approximately 4 to 5 mmol/L in patients with type 2 diabetes in Phase 1 studies, suggesting a low risk for treatment-induced hypoglycemia. The reductions in RT_G led to increased UGE in subjects with type 2 diabetes treated with either 100 mg or 300 mg of canagliflozin ranging from 77 to 119 g/day across the Phase 1 studies; the UGE observed translates to a loss of 308 to 476 kcal/day. The reductions in RT_G and increases in UGE were sustained over a 26-week dosing period in patients with type 2 diabetes. Moderate increases (generally < 400-500 mL) in daily urine volume were seen that attenuated over several

days of dosing. Urinary uric acid excretion was transiently increased by canagliflozin (increased by 19% compared to baseline on day 1 and then attenuating to 6% on day 2 and 1% on day 13). This was accompanied by a sustained reduction in serum uric acid concentration of approximately 20%.

In a single-dose study in patients with type 2 diabetes, treatment with 300 mg before a mixed meal delayed intestinal glucose absorption and reduced postprandial glucose through both a renal and a non-renal mechanism.

Cardiac electrophysiology

In a randomized, double-blind, placebo-controlled, active-comparator, 4-way crossover study, 60 healthy subjects were administered a single oral dose of canagliflozin 300 mg, canagliflozin 1200 mg (4 times the maximum recommended dose), moxifloxacin, and placebo. No meaningful changes in QT_c interval were observed with either the recommended dose of 300 mg or the 1200 mg dose. At the 1200 mg dose, peak canagliflozin plasma concentrations were approximately 1.4 times the steady-state peak concentrations following a 300 mg once-daily dose.

Clinical Efficacy

Glycemic Control Studies in Patients with Type 2 Diabetes Mellitus

Canagliflozin (Invokana[®]) has been studied as monotherapy, as add-on therapy with metformin, sulfonylurea, metformin and sulfonylurea, metformin and a thiazolidinedione (pioglitazone), and as add-on therapy with insulin (with or without other antihyperglycemic agents). The efficacy of Canagliflozin (Invokana[®]) was compared to a DPP-4 inhibitor (sitagliptin) and a sulfonylurea (glimepiride). Canagliflozin (Invokana[®]) was also evaluated in older patients, patients with moderate renal impairment, and patients with cardiovascular disease or at high risk for cardiovascular disease.

A total of 10,285 patients with type 2 diabetes participated in nine double-blind, controlled clinical efficacy and safety studies conducted to evaluate the effects of Canagliflozin (Invokana[®]) on glycemic control. The racial distribution was 72% White, 16% Asian, 4% Black, and 8% other groups. Approximately 16% of patients were Hispanic. Approximately 58% of patients were male. Patients had an overall mean age of 59.6 years (range 21 to 96 years), with 3,082 patients 65 years of age and older and 510 patients ≥ 75 years of age. One study was conducted in patients with moderate renal impairment with an eGFR 30 to < 50 mL/min/1.73 m² (N=269) and three other studies included patients with moderate renal impairment (eGFR 30 to < 60 mL/min/1.73 m²) (N=816).

In patients with type 2 diabetes, treatment with Canagliflozin (Invokana[®]) produced clinically and statistically significant improvements in A_{1c}, fasting plasma glucose (FPG), and 2-hour postprandial glucose (PPG), compared to placebo. Canagliflozin (Invokana[®]) was effective in reducing A_{1c} in a broad range of patients regardless of disease duration and concomitant use of antihyperglycemic agents to treat type 2 diabetes. Statistically significant improvements in glycemic control relative to placebo were observed with Canagliflozin (Invokana[®]) when given as monotherapy, as initial add-on therapy with metformin or a sulfonylurea, add-on therapy with metformin and a sulfonylurea, metformin and pioglitazone, or add-on therapy with insulin (with or without other antihyperglycemic agents). In addition, significant improvements in A_{1c} were observed with Canagliflozin (Invokana[®]) in subjects with moderate renal impairment (eGFR 30 to < 60 mL/min/1.73 m²) and in older patients. Reductions in A_{1c} were observed across subgroups including age, gender, race, baseline body mass index (BMI), and baseline beta-cell function. Greater reductions in A_{1c} relative to placebo were observed in patients with higher baseline A_{1c} or eGFR values (see ***Pharmacokinetic Properties***).

Monotherapy

A total of 584 patients with inadequate glycemic control (A_{1c} of ≥ 7% to ≤ 10%) with diet and exercise participated in a randomized, double-blind, placebo-controlled, parallel-group, 3-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana[®]) over 26 weeks. The mean age was 55 years, 44% of patients were men, and the mean baseline eGFR was 87 mL/min/1.73 m². Patients taking other antihyperglycemic agents (N=281) discontinued the agent and underwent a diet, exercise, and drug washout period of approximately 8 weeks immediately followed by a 2-week, single-blind, placebo run-in period. Patients not taking an oral antihyperglycemic agent (off therapy for at least 8 weeks) (N=303) with

inadequate glycemic control entered a 2-week, single-blind, placebo run-in period. Patients were randomized to take Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, or placebo, administered once daily. As shown in Table 7, statistically significant ($p < 0.001$) improvements in A_{1c} , FPG, PPG, body weight, and systolic blood pressure relative to placebo were observed. In addition, a greater percentage of patients achieved an $A_{1c} < 7.0\%$ compared to placebo.

Patients who were not eligible for inclusion in the main placebo-controlled study due to more severe hyperglycemia ($A_{1c} > 10$ and $\leq 12\%$) participated in a separate active-treatment substudy ($N=91$) and were treated with either Canagliflozin (Invokana®) 100 mg or Canagliflozin (Invokana®) 300 mg (see Table 7).

Add-on therapy

Add-on therapy with metformin

A total of 1,284 patients with inadequate glycemic control (A_{1c} of $\geq 7\%$ to $\leq 10.5\%$) on metformin monotherapy (2000 mg/day or at least 1500 mg/day if higher dose not tolerated) participated in a randomized, double-blind, placebo- and active-controlled, parallel-group, 4-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana®) and add-on therapy with metformin over 26 weeks. The mean age was 55 years, 47% of patients were men, and the mean baseline eGFR was 89 mL/min/1.73 m². Patients already on metformin (N=1009) at screening with inadequate glycemic control completed a 2-week, single-blind, placebo run-in period. Other patients on metformin and another oral agent or a lower than required dose of metformin (N=275) were switched to a regimen of metformin monotherapy. After at least 8 weeks on a stable dose of metformin monotherapy, patients entered a 2-week, single-blind, placebo run-in period. Patients were randomized to the addition of Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, sitagliptin 100 mg, or placebo, administered once daily.

As shown in Table 8, statistically significant (p<0.001) improvements in A_{1c} , FPG, PPG, body weight, and systolic blood pressure relative to placebo were observed. In addition, a greater percentage of patients achieved an $A_{1c} < 7.0\%$ compared to placebo. Fewer patients on Canagliflozin (Invokana®) required glycemic rescue therapy: 1.6% of patients receiving Canagliflozin (Invokana®) 100 mg, 0.3% of patients receiving Canagliflozin (Invokana®) 300 mg, and 14.8% of patients receiving placebo.

Initial combination therapy with metformin

A total of 1,186 patients with type 2 diabetes inadequately controlled with diet and exercise participated in a 26-week double-blind, active-controlled, parallel-group, 5-arm, multicenter study to evaluate the efficacy and safety of initial therapy with Canagliflozin (Invokana®) in combination with metformin XR. The median age was 56 years, 48% of patients were men, and the mean baseline eGFR was 87.6 mL/min/1.73 m². After completing a 2-week single-blind placebo run-in period, patients were randomly assigned for a double-blind treatment period of 26 weeks to 1 of 5 treatment groups (Table 9). The metformin XR dose was initiated at 500 mg/day for the first week of treatment and then increased to 1000 mg/day. Metformin XR or matching placebo was up-titrated based on glycemic criteria to a maximum daily dose of 2000 mg/day, as tolerated. The median dose of metformin XR achieved was 2000 mg.

At the end of treatment, Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg in combination with metformin XR resulted in a statistically significant greater improvement in HbA_{1c} compared to their respective Canagliflozin (Invokana®) doses (100 mg and 300 mg) alone or metformin XR alone. Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg in combination with metformin XR also led to a statistically significant greater proportion of patients with an HbA_{1c} < 7% and a statistically significant reduction in body weight at Week 26 compared with metformin XR alone. Canagliflozin (Invokana®) 100 mg and Canagliflozin (Invokana®) 300 mg as monotherapy demonstrated non-inferiority in HbA_{1c}-lowering compared with metformin XR alone and provided a statistically significant greater reduction in body weight compared with metformin XR alone (see Table 9).

Table 9: Results from 26-Week Active-Controlled Clinical Study of Canagliflozin (Invokana®) as Initial Combination Therapy with Metformin*

Figure 1: Mean Change from Baseline in HbA_{1c} (%) Over Time (mITT Population)

Active-controlled study versus glimepiride as add-on therapy with metformin

A total of 1,450 patients with inadequate glycemic control (A_{1c} level of ≥ 7% to ≤ 9.5%) on metformin monotherapy (≥ 2000 mg/day or at least 1500 mg/day if higher dose not tolerated) participated in a randomized, double-blind, active-controlled, parallel-group, 3-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana®) as add-on therapy with metformin over 52 weeks. The mean age was 56 years, 52% of patients were men, and the mean baseline eGFR was 90 mL/min/1.73 m². Patients on metformin (N=928) at a stable protocol-specified dose entered a 2-week, single-blind, placebo run-in period. Other patients (N=522) entered a metformin dose titration and dose stabilization/antihyperglycemic agent

washout period, immediately followed by the 2-week run-in period. Following the run-in period, patients with inadequate glycemic control were randomized to the addition of Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, or glimepiride (titration allowed throughout the 52-week study to 6 to 8 mg), administered once daily.

As shown in Table 10 and Figure 2, after 52 weeks, treatment with Canagliflozin (Invokana®) 100 mg provided similar reductions in A_{1c} from baseline compared to glimepiride (with the upper bound of the 95% confidence interval around the between-group difference less than the pre-specified non-inferiority margin of 0.3%); Canagliflozin (Invokana®) 300 mg provided a superior (p<0.05) reduction from baseline in A_{1c} compared to glimepiride (with the upper bound of the 95% confidence interval below 0). Statistically significant (p<0.001) improvements in body weight were observed with Canagliflozin (Invokana®) compared to glimepiride. The incidence of hypoglycemia with Canagliflozin (Invokana®) was significantly lower (p<0.001) compared to glimepiride. Fewer patients on Canagliflozin (Invokana®) required glycemic rescue therapy: 6.6% of patients receiving Canagliflozin (Invokana®) 100 mg, 4.9% of patients receiving Canagliflozin (Invokana®) 300 mg, and 10.6% of patients receiving glimepiride.

A subset of patients (N=208) who underwent DXA and abdominal CT scans for evaluation of body composition demonstrated that approximately two-thirds of the weight loss with canagliflozin was due to loss of fat mass with similar amounts of visceral and abdominal subcutaneous fat being lost.

⁴ p<0.001

⁵ Includes only patients who had both baseline and post-baseline values

Figure 2: Mean Changes from Baseline for A_{1c} (%) and Body Weight Over 52 Weeks in a Study Comparing Canagliflozin (Invokana[®]) to Glimepiride as Add-on Therapy with Metformin

Add-on therapy with sulfonylurea

A total of 127 patients with inadequate glycemic control (A_{1c} of $\geq 7\%$ to $\leq 10.5\%$) on sulfonylurea monotherapy participated in a randomized, double-blind, placebo-controlled, parallel-group, 3-arm, multicenter substudy of a cardiovascular study to evaluate the efficacy of Canagliflozin (Invokana[®]) as add-on therapy with sulfonylurea over 18 weeks. The mean age was 65 years, 57% of patients were men, and the mean baseline eGFR was 69 mL/min/1.73 m². Patients on sulfonylurea monotherapy at a stable protocol-specified dose ($\geq 50\%$ maximal dose) for at least 10 weeks completed a 2-week, single-blind, placebo run-in period. After the run-in period, patients with inadequate glycemic control were randomized to the addition of Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, or placebo, administered once daily.

As shown in Table 11, statistically significant ($p < 0.001$) improvements in A_{1c} and FPG relative to placebo were observed at Week 26. In addition, a greater percentage of patients achieved an A_{1c} $< 7.0\%$ compared to placebo. Fewer patients on Canagliflozin (Invokana[®]) required glycemic rescue therapy: 4.8% of patients receiving Canagliflozin (Invokana[®]) 100 mg, 0.0% of patients receiving Canagliflozin (Invokana[®]) 300 mg, and 17.8% of patients receiving placebo. Patients treated with Canagliflozin (Invokana[®]) 300 mg exhibited reductions in body weight compared to placebo. An increased incidence of hypoglycemia was observed in this study, consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to sulfonylurea (see **Special Warnings and Special Precautions for Use and Undesirable Effects**).

Add-on therapy with metformin and sulfonylurea

A total of 469 patients with inadequate glycemic control (A_{1c} level of ≥7% to ≤10.5%) on the combination of metformin (2000 mg/day or at least 1500 mg/day if higher dose not tolerated) and sulfonylurea (maximal or near-maximal effective dose) participated in a randomized, double-blind, placebo-controlled, parallel-group, 3-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana®) as add-on therapy with metformin and sulfonylurea over 26 weeks. The mean age was 57 years, 51% of patients were men, and the mean baseline eGFR was 89 mL/min/1.73 m². Patients on near-maximal or maximal effective doses of metformin and sulfonylurea (N=372) entered a 2-week, single-blind, placebo run-in period. Other patients (N=97) entered a metformin and sulfonylurea dose titration and dose stabilization/antihyperglycemic agent washout period of up to 12 weeks, immediately followed by the 2-week run-in period. Following the run-in period, patients with inadequate glycemic control were randomized to the addition of Canagliflozin (Invokana®) 100 mg, Canagliflozin (Invokana®) 300 mg, or placebo administered once daily. As shown in Table 12, statistically significant (p<0.001) improvements in A_{1c}, FPG, and body weight relative to placebo were observed. In addition, a greater percentage of patients achieved an A_{1c} < 7.0% compared to placebo. Fewer patients on Canagliflozin (Invokana®) required glycemic rescue therapy: 1.3% of patients receiving Canagliflozin (Invokana®) 100 mg, 1.9% of patients receiving Canagliflozin (Invokana®) 300 mg, and 12.8% of patients receiving placebo. An increased incidence of hypoglycemia was observed in this study, consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to sulfonylurea (see **Special Warnings and Special Precautions for Use and Undesirable Effects**).

Active-controlled study versus sitagliptin as add-on therapy with metformin and sulfonylurea

A total of 755 patients with inadequate glycemic control (A_{1c} level of ≥ 7.0% to ≤ 10.5%) on the combination of metformin (2000 mg/day or at least 1500 mg/day if higher dose not tolerated) and sulfonylurea (near-maximal or maximal effective dose) participated in a double-blind, active-controlled, parallel-group, 2-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana®) 300 mg as add-on therapy with metformin and sulfonylurea versus sitagliptin 100 mg as add-on therapy with metformin and sulfonylurea over 52 weeks. The mean age was 57 years, 56% of patients were men, and the mean baseline eGFR was 88 mL/min/1.73 m². Patients on near-maximal or maximal effective doses of metformin and sulfonylurea (N=716) entered a 2-week single-blind, placebo run-in period. Other patients (N=39) entered a metformin and sulfonylurea dose titration and dose stabilization period of up to 12 weeks, immediately followed by the 2-week run-in period. Following the run-in period, patients with inadequate glycemic control were randomized to the addition of Canagliflozin (Invokana®) 300 mg or sitagliptin 100 mg.

As shown in Table 13 and Figure 3, after 52 weeks, Canagliflozin (Invokana®) 300 mg provided a superior (p<0.05) reduction in A_{1c} compared to sitagliptin 100 mg (with the upper bound of the 95% confidence interval around the between-group difference below 0). In addition, a greater percent of patients achieved an A_{1c} of < 7.0% with Canagliflozin (Invokana®) 300 mg relative to sitagliptin: 47.6% of patients receiving Canagliflozin (Invokana®) 300 mg and 35.3% of patients receiving sitagliptin. Patients treated with Canagliflozin (Invokana®) 300 mg exhibited a significant mean decrease in percent change from baseline body weight compared to patients administered sitagliptin 100 mg. A similar increased incidence of hypoglycemia was observed with both Canagliflozin (Invokana®) 300 mg and sitagliptin in this study, consistent with the expected increase of hypoglycemia when agents not associated with hypoglycemia are added to sulfonylurea (see **Special Warnings and Special Precautions for Use** and **Undesirable Effects**). The

proportion of patients who met glycemic withdrawal criteria (based on FPG until Week 26 and A_{1c} thereafter) was lower with Canagliflozin (Invokana[®]) 300 mg (10.6%) compared with sitagliptin 100 mg (22.5%).

Table 13: Results from 52-Week Clinical Study Comparing Canagliflozin (Invokana[®]) to Sitagliptin as Add-on Therapy with Metformin and Sulfonylurea¹

Add-on therapy with metformin and pioglitazone

A total of 342 patients with inadequate glycemic control (A_{1c} level of $\geq 7.0\%$ to $\leq 10.5\%$) on the combination of metformin (2000 mg/day or at least 1500 mg/day if higher dose not tolerated) and pioglitazone (30 or 45 mg/day) participated in a randomized, double-blind, placebo-controlled, parallel-group, 3-arm, multicenter clinical study to evaluate the efficacy of Canagliflozin (Invokana[®]) as add-on therapy with metformin and pioglitazone over 26 weeks. The mean age was 57 years, 63% of patients were men, and the mean baseline eGFR was 86 mL/min/1.73 m². Patients already on protocol-specified doses of metformin and pioglitazone (N=163) entered a 2-week, single-blind, placebo run-in period. Other patients (N=181) entered a metformin and pioglitazone dose titration and dose stabilization period for up to 12 weeks with at least 8 weeks on stable doses of metformin and pioglitazone, immediately followed by the 2-week run-in period. Following the run-in period, patients with inadequate glycemic control were randomized (N=344) to the addition of Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, or placebo, administered once daily. As shown in Table 14, statistically significant ($p < 0.001$) improvements in A_{1c} , FPG, and body weight relative to placebo were observed for Canagliflozin (Invokana[®]) at Week 26. In addition, a greater percent of patients achieved an A_{1c} of $< 7.0\%$ compared to placebo. Fewer patients on Canagliflozin (Invokana[®]) required glycemic rescue therapy: 0.9% of patients receiving Canagliflozin (Invokana[®]) 100 mg, 0.0% of patients receiving Canagliflozin (Invokana[®]) 300 mg, and 12.2% of patients receiving placebo.

Add-on combination therapy with metformin and dipeptidyl-peptidase-4 inhibitor

A total of 213 patients with type 2 diabetes inadequately controlled on the combination of metformin (greater than or equal to 1500 mg/day) and sitagliptin 100 mg/day (or equivalent fixed-dose combination) participated in a 26-week, double-blind, placebo-controlled study to evaluate the efficacy and safety of Canagliflozin (Invokana[®]) in combination with metformin and sitagliptin. The mean age was 57 years, 57% of patients were men, and the mean baseline eGFR was 90.5 mL/min/1.73 m². Patients already on the protocol-specified doses of metformin and sitagliptin (N=213) entered a 2-week, single-blind, placebo run-in period. Following the run-in period, patients were randomized to Canagliflozin (Invokana[®]) 100 mg or placebo, administered once daily as add-on to metformin and sitagliptin. Up-titration to Canagliflozin (Invokana[®]) 300 mg was made as early as Week 6 in patients requiring additional glycemic control who had appropriate eGFR and who were tolerating Canagliflozin (Invokana[®]) 100 mg.

At the end of treatment, Canagliflozin (Invokana[®]) once daily resulted in a statistically significant improvement in HbA_{1c} (p<0.001) compared to placebo when added to metformin and sitagliptin. Canagliflozin (Invokana[®]) once daily also resulted in a statistically significant improvement in the proportion of patients achieving an HbA_{1c} less than 7%, a statistically significant reduction in fasting plasma glucose (FPG), and in percent body weight reduction compared to placebo when added to metformin and sitagliptin (see Table 15). A statistically significant (p<0.001) mean change from baseline in systolic blood pressure relative to placebo of -5.85 mmHg was observed with Canagliflozin (Invokana[®]) once daily. For patients taking Canagliflozin (Invokana[®]), the percentage experiencing an adverse event or discontinuing due to an adverse event occurred in 39.8% and 0.9%, respectively as compared with placebo which occurred in 44.4% and 2.8%, respectively.

Table 15: Results from 26-Week Placebo-Controlled Clinical Study of Canagliflozin (Invokana[®]) in Combination with Metformin and Sitagliptin*

Efficacy Parameter	Placebo + Metformin and Sitagliptin (N=106)	Canagliflozin (Invokana[®]) + Metformin and Sitagliptin (N=107)

Add-on therapy with insulin (with or without other antihyperglycemic agents)

A total of 1,718 patients with inadequate glycemic control (A_{1c} level of ≥ 7.0 to $\leq 10.5\%$) on insulin ≥ 30 units/day or insulin add-on therapy with other antihyperglycemic agents participated in a randomized, double-blind, placebo-controlled, parallel-group, 3-arm, multicenter substudy of a cardiovascular study; this substudy evaluated the efficacy of Canagliflozin (Invokana[®]) as add-on therapy with insulin (with or without other antihyperglycemic agents) over 18 weeks. The mean age was 63 years, 66% of patients were men, and the mean baseline eGFR was 75 mL/min/1.73 m². Patients on basal, bolus, or basal/bolus insulin, with the majority on a background basal/bolus insulin regimen, for at least 10 weeks entered a 2-week, single-blind, placebo run-in period. After the run-in period, patients with inadequate glycemic control were randomized to the addition of Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, or placebo, administered once daily. The mean daily insulin dose at baseline was 83 units, which was similar across treatment groups.

As shown in Table 16, statistically significant ($p < 0.001$) improvements in A_{1c} , FPG, and body weight relative to placebo were observed for Canagliflozin (Invokana[®]) at Week 18. In addition, a greater percentage of patients achieved an $A_{1c} < 7.0\%$ compared to placebo. Fewer patients on Canagliflozin (Invokana[®]) required glycemic rescue therapy: 4.1% of patients receiving Canagliflozin (Invokana[®]) 100 mg, 3.1% of patients receiving Canagliflozin (Invokana[®]) 300 mg, and 8.7% of patients receiving placebo. An increased incidence of hypoglycemia was observed in this study, which is consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to insulin (see **Special Warnings and Special Precautions for Use** and **Undesirable Effects**).

Studies in special populations

Study in older patients

A total of 714 older patients (≥ 55 to ≤ 80 years of age) with inadequate glycemic control (baseline A_{1c} level of ≥ 7.0 to $\leq 10.0\%$) on current diabetes therapy (either diet and exercise alone or in combination with oral or parenteral agents) participated in a randomized, double-blind, placebo-controlled study to evaluate the efficacy of Canagliflozin (Invokana[®]) as add-on therapy with current diabetes treatment over 26 weeks. The mean age was 64 years, 55% of patients were men, and the mean baseline eGFR was 77 mL/min/1.73 m². Patients with inadequate glycemic control on their current diabetes therapy were randomized to the addition of Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, or placebo, administered once daily. As shown in Table 17, statistically significant ($p < 0.001$) changes from baseline in A_{1c} , FPG, and body weight were observed for Canagliflozin (Invokana[®]) at Week 26. In addition, a greater percent of patients achieved an A_{1c} of $< 7.0\%$ compared to placebo. Fewer patients on Canagliflozin (Invokana[®]) required glycemic rescue therapy: 2.1% of patients receiving Canagliflozin (Invokana[®]) 100 mg, 0.4% of patients receiving Canagliflozin (Invokana[®]) 300 mg, and 11.0% of patients receiving placebo (see **Pharmacokinetic Properties - Special populations**).

A subset of patients (N=211) participated in the body composition substudy using DXA body composition analysis. This demonstrated that approximately two-thirds of the weight loss with Canagliflozin (Invokana[®]) was due to loss of fat mass relative to placebo. There were no meaningful changes in bone density in trabecular and cortical regions.

Patients with renal impairment

A total of 269 patients with moderate renal impairment and eGFR 30 to < 50 mL/min/1.73 m² inadequately controlled on current diabetes therapy (baseline A_{1c} level of ≥ 7.0 to $\leq 10.5\%$) participated

in a randomized, double-blind, placebo-controlled clinical study to evaluate the efficacy of Canagliflozin (Invokana[®]) as add-on therapy with current diabetes treatment (diet or antihyperglycemic agent therapy with most patients on insulin and/or sulfonylurea) over 26 weeks. The mean age was 68 years, 61% of patients were men, and the mean baseline eGFR was 39 mL/min/1.73 m². Patients with inadequate glycemic control on their current diabetes therapy were randomized to the addition of Canagliflozin (Invokana[®]) 100 mg, Canagliflozin (Invokana[®]) 300 mg, or placebo administered once daily.

As shown in Table 18, significant improvements in A_{1c} relative to placebo were observed for Canagliflozin (Invokana[®]) 100 mg and Canagliflozin (Invokana[®]) 300 mg, respectively at Week 26. In addition, a greater percentage of patients achieved an A_{1c} < 7.0% compared to placebo. Fewer patients on Canagliflozin (Invokana[®]) required glycemic rescue therapy: 4.4% of patients receiving Canagliflozin (Invokana[®]) 100 mg, 3.4% of patients receiving Canagliflozin (Invokana[®]) 300 mg, and 14.4% of patients receiving placebo. Patients treated with Canagliflozin (Invokana[®]) exhibited mean decreases in percent change from baseline body weight compared to placebo. An increased incidence of hypoglycemia was observed in this study, consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to insulin and/or sulfonylurea (see **Special Warnings and Special Precautions for Use, Undesirable Effects, and Pharmacokinetic Properties - Special populations**).

Integrated analysis of patients with moderate renal impairment

An analysis of a pooled patient population (N=1085) with moderate renal impairment (baseline eGFR 30 to < 60 mL/min/1.73 m²) from four placebo-controlled studies was conducted to evaluate the change from baseline A_{1c} and percent change from baseline in body weight in these patients. The mean eGFR in this analysis was 48 mL/min/1.73 m², which was similar across all treatment groups. Most patients were on insulin and/or sulfonylurea.

This analysis demonstrated that Canagliflozin (Invokana[®]) provided statistically significant (p<0.001) improvements in A_{1c} and body weight compared to placebo (see Table 19). An increased incidence of hypoglycemia was observed in this integrated analysis, consistent with the expected increase of hypoglycemia when an agent not associated with hypoglycemia is added to insulin and/or sulfonylurea (see **Special Warnings and Special Precautions for Use** and **Undesirable Effects**).

Cardiovascular outcomes

The effect of Canagliflozin (Invokana[®]) on cardiovascular risk in adults with type 2 diabetes who had established cardiovascular (CV) disease or were at risk for CVD (two or more CV risk factors), was evaluated in the CANVAS Program (CANVAS and CANVAS-R studies). These studies were multicenter, multi-national, randomized, double-blind parallel group, with similar inclusion and exclusion criteria and patient populations. The studies compared the risk of experiencing a Major Adverse Cardiovascular Event (MACE) defined as the composite of cardiovascular death, nonfatal myocardial infarction and nonfatal stroke, between Canagliflozin (Invokana[®]) and placebo on a background of standard of care treatments for diabetes and atherosclerotic cardiovascular disease.

In CANVAS, subjects were randomly assigned 1:1:1 to canagliflozin 100 mg, canagliflozin 300 mg, or matching placebo. In CANVAS-R, subjects were randomly assigned 1:1 to canagliflozin 100 mg or matching placebo, and titration to 300 mg was permitted at the investigator's discretion (based on tolerability and glycemic needs) after Week 13. Concomitant antidiabetic and atherosclerotic therapies could be adjusted, at the discretion of investigators, to ensure participants were treated according to the standard care for these diseases.

A total of 10,134 patients were treated (4,327 in CANVAS and 5,807 in CANVAS-R; total of 4,344 randomly assigned to placebo and 5,790 to canagliflozin) and exposed for a mean of 149 weeks (exposed for a mean of 223 weeks in CANVAS and 94 weeks in CANVAS-R). Vital status was obtained for 99.6% of subjects across the studies. Approximately 78% of the study population was Caucasian, 13% was Asian, and 3% was Black. The mean age was 63 years and approximately 64% were male.

All patients in the study had inadequately controlled type 2 diabetes mellitus at screening (HbA_{1c} ≥7.0% to ≤10.5%). The mean HbA_{1c} at baseline was 8.2% and mean duration of diabetes was 13.5 years. Approximately 31%, 21% and 18% reported a past history of neuropathy, retinopathy and nephropathy, respectively. Baseline renal function was normal or mildly impaired in 80% of patients and moderately impaired in 20% of patients (mean eGFR 77 mL/min/1.73 m²). At baseline, patients were treated with one or more antidiabetic medications including metformin (77%), insulin (50%), and sulfonylurea (43%).

Sixty-six percent of subjects had a history of established cardiovascular disease, with 56% having a history of coronary disease, 19% with cerebrovascular disease, and 21% with peripheral vascular disease; 14% had a history of heart failure. At baseline, the mean systolic blood pressure was 137 mmHg, the mean diastolic blood pressure was 78 mmHg, the mean LDL was 89 mg/dL, the mean HDL was 46 mg/dL, and the mean urinary albumin to creatinine ratio (UACR) was 115 mg/g. At baseline, approximately 80% of patients were treated with renin angiotensin system inhibitors, 54% with beta-blockers, 13% with loop diuretics, 36% with non-loop diuretics, 75% with statins, and 74% with antiplatelet agents (mostly aspirin).

The primary endpoint in the CANVAS Program was the time to first occurrence of a MACE. The MACE HR in patients treated with canagliflozin compared with placebo and its 95% CI was estimated using a stratified Cox proportional hazards regression model with stratification by study and by established cardiovascular disease.

Canagliflozin (Invokana®) significantly reduced to the risk of first occurrence of the primary composite endpoint of cardiovascular death, nonfatal myocardial infarction, and nonfatal stroke (HR: 0.86; 95% CI 0.75, 0.97). Each MACE component contributed to the overall composite, as shown in Figure 4. Results for the 100 mg and 300 mg canagliflozin doses were consistent with results for the combined dose groups. The efficacy of Canagliflozin (Invokana®) on MACE was generally consistent across major demographic and disease subgroups, including presence or absence of established cardiovascular disease.

There were 2,011 patients with eGFR 30 to < 60 mL/min/1.73 m². The MACE findings in this subgroup were consistent with the overall findings (see Figure 6).

Figure 4: Treatment Effect for the Primary Composite Endpoint and its Components

¹ *P* value for superiority (2-sided) = 0.0158.

Based on the Kaplan-Meier plot for the first occurrence of MACE, shown below, the reduction in MACE in the canagliflozin group was observed as early as Week 26 and was maintained throughout the remainder of the study.

Figure 5: Time to First Occurrence of MACE

Figure 6: Effects of Canagliflozin on the Primary Cardiovascular Outcome (MACE) in Subgroups

NOTE: The figure above presents effects of MACE in various subgroups most of which are baseline characteristics and which were pre-specified (except heart failure, as noted by the asterisk). The 95% confidence intervals (CIs) that are shown do not take into account how many comparisons were made, nor do they reflect the effect of a particular factor after adjustment of other factors. Apparent homogeneity or heterogeneity among groups should not be over-interpreted. The p value of <0.05 represents significance for subgroup heterogeneity.

Renal Outcomes

The Canagliflozin and Renal Events in Diabetes with Established Nephropathy Clinical Evaluation Trial (CREDENCE) studied the effect of Canagliflozin (Invokana®) 100 mg relative to placebo on progression to end-stage kidney disease (ESKD), doubling of serum creatinine, and renal or cardiovascular (CV) death in adults with type 2 diabetes and diabetic kidney disease (DKD) with (eGFR) ≥ 30 to < 90 mL/min/1.73 m² [CrCl ≥ 30 to < 90 mL/min] and albuminuria (> 300 to ≤ 5000 mg/g of creatinine), who were receiving standard of care including angiotensin-converting-enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB). This study was a multicenter, randomized, double-blind, event-driven, placebo-controlled, parallel-group, 2-arm study.

In CREDENCE, subjects were randomly assigned 1:1 to Canagliflozin (Invokana®) 100 mg or placebo, stratified by screening estimated glomerular filtration rate (eGFR) ≥ 30 to < 45 , ≥ 45 to < 60 , ≥ 60 to < 90 mL/min/1.73 m² [CrCl ≥ 30 to < 45 , ≥ 45 to < 60 , ≥ 60 to < 90 mL/min]. Treatment with Canagliflozin (Invokana®) 100 mg was continued in patients until the initiation of dialysis or in the event of renal transplantation.

A total of 4,401 subjects were randomized (2,199 randomly assigned to placebo and 2,202 to Canagliflozin (Invokana®) 100 mg). Four of the randomized subjects were not dosed, leading to 4,397 subjects (exposed for a mean of 115 weeks) in both On-Study and On-Treatment analysis sets. Vital status was obtained for 99.9% of subjects across the study. The majority (67%) of the study population identified as White, 20% as Asian, and 5% as Black; 32% of all subjects were of Hispanic or Latino ethnicity. The mean age was 63 years and approximately 66% were male.

The mean baseline HbA1c was 8.3%, with 53.2% of subjects having baseline HbA1c $\geq 8\%$, and baseline median urine albumin/creatinine was 927 mg/g. The most frequent antihyperglycemic agents (AHA) medications used at baseline were insulin (65.5%), biguanides (57.8%), and sulfonylureas (28.8%). Nearly all subjects (99.9%) were on ACEi or ARB at randomization. About 92% of the subjects were on cardiovascular therapies (not including ACEi/ARBs) at baseline, with approximately 60% taking an anti-thrombotic agent (including aspirin) and 69% on statins.

The mean baseline eGFR was 56.2 mL/min/1.73 m² [CrCl 56.2 mL/min] and approximately 60% of the population had a baseline eGFR of < 60 mL/min/1.73 m² [CrCl < 60 mL/min]. Subjects had a mean duration of diabetes of approximately 16 years. The proportion of subjects with prior CV disease was 50.4%; 14.8% had a history of heart failure. While the entire study population had nephropathy at baseline, about 64% of the population had at least 2 microvascular complications (i.e. diabetic nephropathy and another microvascular complication).

The primary composite endpoint in the CREDENCE study was the time to first occurrence of ESKD (defined as an eGFR < 15 mL/min/1.73 m² [CrCl < 15 mL/min], initiation of chronic dialysis or renal transplant), doubling of serum creatinine, and renal or CV death.

Canagliflozin (Invokana®) 100 mg significantly reduced the risk of first occurrence of the primary composite endpoint of ESKD, doubling of serum creatinine, and renal or CV death [$p < 0.0001$; HR: 0.70; 95% CI: 0.59, 0.82] (see Figure 8). Additionally, each individual component was consistent with the overall results of the primary composite endpoint as shown in Figure 7. The efficacy of Canagliflozin (Invokana®) 100 mg on primary endpoint composite was generally consistent across major demographic and disease subgroups, including all three eGFR strata and subjects with or without a history of CV disease.

Canagliflozin (Invokana®) 100 mg significantly reduced the risk of the following secondary endpoints, as shown in Figure 7 below: Composite endpoint of CV Death and Hospitalized Heart Failure [HR: 0.69; 95% CI: 0.57 to 0.83; $p = 0.0001$], MACE (Major Adverse Cardiovascular Events) (comprised of non-fatal MI, non-fatal stroke and CV death) [HR: 0.80; 95% CI: 0.67 to 0.95; $p = 0.0121$], Hospitalized Heart Failure [HR: 0.61; 95% CI: 0.47 to 0.80; $p = 0.0003$], and Renal composite endpoint (comprised of ESKD, doubling of serum creatinine, and renal death) [HR: 0.66; 95% CI: 0.53 to 0.81; $p < 0.0001$]. For both primary and secondary endpoints, the HR in subjects treated with Canagliflozin (Invokana®) 100 mg compared with placebo and its 95% CI was estimated using a stratified Cox proportional hazards regression model with treatment as the

explanatory variable and stratified by screening eGFR (≥ 30 to < 45 , ≥ 45 to < 60 , ≥ 60 to < 90 mL/min/1.73 m²) [CrCl ≥ 30 to < 45 , ≥ 45 to < 60 , ≥ 60 to < 90 mL/min].

Figure 7: Treatment Effect for the Primary and Secondary Composite Endpoints and their Components
Forest Plot of Hazard Ratios and 95% CI of the Primary Composite Endpoint and Secondary Endpoints (Intention-to-Treat Analysis Set)

CI, confidence interval; ESKD, end-stage kidney disease; CV, cardiovascular; NS, not significant; HHF, hospitalization for heart failure; MI, myocardial infarction.
*CV death is being presented as both a component of the primary composite endpoint and a secondary endpoint which underwent formal hypothesis testing.

Based on the Kaplan-Meier plot for the time to first occurrence of the primary composite endpoint shown below, the treatment effect was evident beginning from Week 52 with Canagliflozin (Invokana®) 100 mg and was maintained through the end of study.

Figure 8: CREDENCE: Time to First Occurrence of the Primary Composite Endpoint

As shown in Figure 9, the eGFR in placebo-treated patients demonstrated a progressive linear decline over time; in contrast, the canagliflozin group showed an acute decrease at Week 3, followed by an attenuated decline over time; after Week 52, the LS mean decrease in eGFR was smaller in the canagliflozin group than in the placebo group, and the treatment effect was maintained through the end of treatment.

Figure 9: LS Mean Change From Baseline in eGFR Over Time (On-Treatment Analysis Set)

Diabetic comorbidities

Blood pressure

In an analysis of four 26-week, placebo-controlled studies (N=2313), mean reductions in systolic blood pressure relative to placebo were observed with Canagliflozin (Invokana®) 100 mg (-3.9 mmHg), Canagliflozin (Invokana®) 300 mg (-5.3 mmHg), and placebo (-0.1 mmHg) regardless of antihypertensive medication use at baseline. In this same population, there was a smaller effect on diastolic blood pressure with mean changes of -2.1 mmHg with Canagliflozin (Invokana®) 100 mg, -2.5 mmHg with Canagliflozin (Invokana®) 300 mg, and -0.3 mmHg with placebo, regardless of antihypertensive medication use at baseline. There was no discernible change in heart rate.

Lipid effects

In an integrated analysis of four placebo-controlled studies of 26 weeks, patients with type 2 diabetes treated with both doses of Canagliflozin (Invokana®) had increased serum levels of total cholesterol, LDL-C, and HDL-C (high-density lipoprotein cholesterol) compared to small changes in placebo, while serum levels of triglycerides decreased compared to placebo (see Table 20). At Week 26, the LDL-C/HDL-C ratio minimally changed compared to baseline in all three treatment groups. Similar to changes in non-HDL-C, apolipoprotein B and LDL-C particle number (measured in the monotherapy and 26-week metformin add-on therapy study) increased to a smaller extent compared to LDL-C changes (see **Undesirable Effects**).

Table 20: Effect of Canagliflozin (Invokana®) on Lipid Measurements in Four 26-Week Placebo-Controlled Studies¹

¹ As monotherapy or add-on therapy with metformin, metformin and sulfonylurea, and metformin and pioglitazone

Patients with baseline HbA_{1c} > 10% to ≤ 12%

A substudy of patients with baseline HbA_{1c} > 10 to ≤ 12% with canagliflozin as monotherapy resulted in reductions from baseline in HbA_{1c} of -2.13% and -2.56% for canagliflozin 100 mg and 300 mg, respectively.

Fasting plasma glucose

In four placebo-controlled studies, treatment with Canagliflozin (Invokana®) as monotherapy or add-on therapy with one or two oral antihyperglycemic drugs resulted in mean changes from baseline relative to placebo in FPG of -1.2 mmol/L to -1.9 mmol/L for Canagliflozin (Invokana®) 100 mg and -1.9 mmol/L

to -2.4 mmol/L for Canagliflozin (Invokana®) 300 mg, respectively. These reductions were sustained over the treatment period and near maximal after the first day of treatment.

Post-prandial glucose

Using a standardized mixed meal tolerance test, post-prandial glucose was measured in three placebo-controlled clinical studies as monotherapy or add-on therapy with one or two oral antihyperglycemic drugs. Canagliflozin (Invokana®) resulted in mean change reductions from baseline relative to placebo in postprandial glucose of -1.5 mmol/L to -2.7 mmol/L for Canagliflozin (Invokana®) 100 mg and -2.1 mmol/L to -3.5 mmol/L for Canagliflozin (Invokana®) 300 mg, respectively, due to reductions in the pre-meal glucose concentration and reduced post-prandial glucose excursions.

Beta-cell function

Clinical studies in a subset of patients with type 2 diabetes (N=297) with Canagliflozin (Invokana®) for 26 weeks indicate improved beta-cell function based on measures such as the homeostasis model assessment for beta-cell function (HOMA2-%B) and the improved insulin secretion rate with mixed-meal tolerance testing.

Hospitalized heart failure

In a long-term cardiovascular outcome study, subjects treated with Canagliflozin (Invokana®) had a lower risk of hospitalized for heart failure compared to those treated with placebo.

Table 21: In a Long-term Cardiovascular Outcome Study, Treatment Effect for Hospitalized Heart Failure and the Composite of Cardiovascular Death and Hospitalized Heart Failure

	Placebo N=4,347 Event rate per 100 patient- years	Canagliflozin (Invokana®) N=5,795 Event rate per 100 patient- years	Hazard ratio vs. Placebo (95% CI)

Pharmacokinetic Properties

The pharmacokinetics of canagliflozin are essentially similar in healthy subjects and patients with type 2 diabetes. After single-dose oral administration of 100 mg and 300 mg in healthy subjects, canagliflozin was rapidly absorbed, with peak plasma concentrations (median T_{max}) occurring 1 to 2 hours post-dose. Plasma C_{max} and AUC of canagliflozin increased in a dose-proportional manner from 50 mg to 300 mg. The apparent terminal half-life ($t_{1/2}$) (expressed as mean \pm standard deviation) was 10.6 ± 2.13 hours and 13.1 ± 3.28 hours for the 100 mg and 300 mg doses, respectively. Steady-state was reached after 4 to 5 days of once-daily dosing with canagliflozin 100 mg to 300 mg. Canagliflozin does not exhibit time-dependent pharmacokinetics, and accumulated in plasma up to 36% following multiple doses of 100 mg and 300 mg.

Absorption

The mean absolute oral bioavailability of canagliflozin is approximately 65%. Co-administration of a high-fat meal with canagliflozin had no effect on the pharmacokinetics of canagliflozin; therefore, Canagliflozin (Invokana[®]) may be taken with or without food. However, based on the potential to reduce postprandial plasma glucose excursions due to delayed intestinal glucose absorption, it is recommended that Canagliflozin (Invokana[®]) preferably be taken before the first meal of the day (see **Posology and Method of Administration**).

Distribution

The mean steady-state volume of distribution of canagliflozin following a single intravenous infusion in healthy subjects was 83.5 L, suggesting extensive tissue distribution. Canagliflozin is extensively bound to proteins in plasma (99%), mainly to albumin. Protein binding is independent of canagliflozin plasma concentrations. Plasma protein binding is not meaningfully altered in patients with renal or hepatic impairment.

Metabolism

O-glucuronidation is the major metabolic elimination pathway for canagliflozin, which is mainly glucuronidated by UGT1A9 and UGT2B4 to two inactive O-glucuronide metabolites. Increases in AUC of canagliflozin (26% and 18%) were observed in subjects carrying the UGT1A9*3 allele and UGT2B4*2

allele, respectively. These increases in canagliflozin exposure are not expected to be clinically relevant. CYP3A4-mediated (oxidative) metabolism of canagliflozin is minimal (approximately 7%) in humans.

Elimination

Following administration of a single oral [¹⁴C] canagliflozin dose to healthy subjects, 41.5%, 7.0%, and 3.2% of the administered radioactive dose was recovered in feces as canagliflozin, a hydroxylated metabolite, and an *O*-glucuronide metabolite, respectively. Enterohepatic circulation of canagliflozin was negligible.

Approximately 33% of the administered radioactive dose was excreted in urine, mainly as *O*-glucuronide metabolites (30.5%). Less than 1% of the dose was excreted as unchanged canagliflozin in urine. Renal clearance for the 100 mg and 300 mg doses ranged from 1.30 to 1.55 mL/min.

Canagliflozin is a low-clearance drug, with a mean systemic clearance of approximately 192 mL/min in healthy subjects following intravenous administration.

Special populations

Renal impairment

A single-dose, open-label study evaluated the pharmacokinetics of canagliflozin 200 mg in subjects with varying degrees of renal impairment [classified using the Modification of Diet in Renal Disease (MDRD)-eGFR formula] compared to healthy subjects. The study included 3 subjects with normal renal function (eGFR \geq 90 mL/min/1.73 m²), 10 subjects with mild renal impairment (eGFR 60 to < 90 mL/min/1.73 m²), 9 subjects with moderate renal impairment (eGFR 30 to < 60 mL/min/1.73 m²), and 10 subjects with severe renal impairment (eGFR 15 to < 30 mL/min/1.73 m²) as well as 8 subjects with end-stage renal disease (ESRD) on hemodialysis.

The C_{max} of canagliflozin was moderately increased by 13%, 29%, and 29% in subjects with mild, moderate, and severe renal failure, respectively, but not in subjects on hemodialysis. Compared to healthy subjects, plasma AUC of canagliflozin was increased by approximately 17%, 63%, and 50% in subjects with mild, moderate, and severe renal impairment, respectively, but was similar for ESRD subjects and healthy subjects (see **Posology and Method of Administration**, **Special Warnings and Special Precautions for Use**, and **Undesirable Effects**).

Canagliflozin was negligibly removed by hemodialysis.

Hepatic impairment

Relative to subjects with normal hepatic function, the geometric mean ratios for C_{max} and AUC_∞ of canagliflozin were 107% and 110%, respectively, in subjects with Child-Pugh class A (mild hepatic impairment) and 96% and 111%, respectively, in subjects with Child-Pugh class B (moderate hepatic impairment) following administration of a single 300 mg dose of canagliflozin.

These differences are not considered to be clinically meaningful. No dose adjustment is necessary in patients with mild or moderate hepatic impairment. There is no clinical experience in patients with Child-Pugh class C (severe) hepatic impairment and, therefore, Canagliflozin (Invokana®) is not recommended for use in this patient population.

Elderly (\geq 65 years of age)

Age had no clinically meaningful effect on the pharmacokinetics of canagliflozin based on a population pharmacokinetic analysis (see **Posology and Method of Administration**, **Special Warnings and Special Precautions for Use** and **Undesirable Effects**).

Pediatrics (< 18 years of age)

A pediatric Phase 1 study examined the pharmacokinetics and pharmacodynamics of canagliflozin in children and adolescents ≥ 10 to < 18 years of age with type 2 diabetes mellitus who were on a stable dose of metformin. The observed pharmacokinetic and pharmacodynamic responses were consistent with those found in adult subjects. The safety and efficacy of Canagliflozin (Invokana®) in the pediatric population have not been established.

Other populations

No dose adjustment is necessary based on gender, race/ethnicity, or body mass index. These characteristics had no clinically meaningful effect on the pharmacokinetics of canagliflozin based on a population pharmacokinetic analysis.

NON-CLINICAL INFORMATION

Non-clinical data reveal no particular hazard for humans based on conventional studies of safety pharmacology, repeated dose toxicity, genotoxicity, and toxicity to reproduction and development. A study in juvenile rats administered canagliflozin from postnatal Day 21 through Day 90 did not show increased sensitivity compared to effects observed in adult rats.

Carcinogenicity and Mutagenicity

Canagliflozin did not increase the incidence of tumors in male and female mice in a 2-year study at doses of 10, 30, and 100 mg/kg. The highest dose of 100 mg/kg provided up to 14 times the clinical dose of 300 mg based on AUC exposure. Canagliflozin increased the incidence of testicular Leydig cell tumors in male rats at all doses tested (10, 30, and 100 mg/kg); the lowest dose of 10 mg/kg is approximately 1.5 times the clinical dose of 300 mg based on AUC exposure. The higher doses of canagliflozin (100 mg/kg) in male and female rats increased the incidence of pheochromocytomas and renal tubular tumors; based on AUC exposure, the No Observable Effect Level (NOEL) of 30 mg/kg/day for pheochromocytomas and renal tubular tumors is approximately 4.5 times the exposure at the daily clinical dose of 300 mg. Based on preclinical and clinical mechanistic studies, the Leydig cell tumors, renal tubule tumors, and pheochromocytomas are considered to be rat-specific. Canagliflozin-induced renal tubule tumors and pheochromocytomas in rats appear to be caused by carbohydrate malabsorption as a consequence of intestinal SGLT1 inhibitory activity of canagliflozin in the gut of rats; mechanistic clinical studies have not demonstrated carbohydrate malabsorption in humans at canagliflozin doses of up to 2-times the maximum recommended clinical dose. The Leydig cell tumors are associated with an increase in luteinizing hormone (LH), which is a known mechanism of Leydig cell tumor formation in rats. In a 12-week clinical study, unstimulated LH did not increase in males treated with canagliflozin.

Canagliflozin was not mutagenic with or without metabolic activation in the Ames assay. Canagliflozin was mutagenic in the in vitro mouse lymphoma assay with but not without metabolic activation. Canagliflozin was not mutagenic or clastogenic in an in vivo oral micronucleus assay in rats and an in vivo oral Comet assay in rats.

Reproductive Toxicology

In a pre- and postnatal development study, canagliflozin administered to female rats from gestation Day 6 to lactation Day 20 resulted in decreased body weights in male and female offspring at maternally toxic doses > 30 mg/kg/day (exposures ≥ 5.9 times the human exposure to canagliflozin at the maximum recommended human dose [MRHD]). Maternal toxicity was limited to decreased body weight gain.

In rat studies, canagliflozin had no adverse effects on early embryonic development, mating, and fertility up to the highest dose of 100 mg/kg (up to 19 times the clinical dose of 300 mg based on AUC exposure).

PHARMACEUTICAL INFORMATION

LIST OF EXCIPIENTS

The canagliflozin tablet core contains croscarmellose sodium, hydroxypropyl cellulose, lactose anhydrous, magnesium stearate, and microcrystalline cellulose. The film-coating contains iron oxide yellow (100 mg tablet only), Macrogol (polyethylene glycol), polyvinyl alcohol, talc and titanium dioxide.

INCOMPATIBILITIES

Not applicable.

SHELF-LIFE

36 months

SPECIAL PRECAUTIONS FOR STORAGE

Store at temperatures not exceeding 30°C.
Keep out of the sight and reach of children.

NATURE AND CONTENTS OF CONTAINER

Canagliflozin (Invokana®) 100 mg tablet: Alu/PVC blister packs 10's. Box of 30 film-coated tablets.
Alu/PVC blister packs 5's. Box of 5 film-coated tablets.

Canagliflozin (Invokana®) 300 mg tablet: Alu/PVC blister packs 10's. Box of 30 film-coated tablets.
Alu/PVC blister packs 5's. Box of 5 film-coated tablets.

INSTRUCTIONS FOR USE AND HANDLING

No special requirements.

CAUTION

Foods, Drugs, Devices and Cosmetics Act prohibits dispensing without prescription.
Patient must seek medical attention immediately at the first sign of any adverse drug reaction. For suspected adverse drug reaction, report to the FDA: www.fda.gov.ph.
